

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at <http://books.google.com/>

## P R E F A C E .

ABOUT three-quarters of a century has elapsed since "Goldsmith's History of the Earth and Animated Nature" was first published ; and, although it has gone through innumerable editions, such is the charm of the work, that the sale continues undiminished. The art which Goldsmith possessed of saying everything in a pleasing manner—the fascinating ease and beauty of his style—and the simple and intelligible arrangement which he adopted—secured for his Work an extensive patronage : and well did he fulfil the correctness of Dr. Johnson's anticipation, when he said—"Goldsmith is now writing a Natural History, and he will make it as entertaining as a Persian tale."

The present edition is completed for about half the price of former editions of this size, so as it may be within the reach of all classes. It is unabridged, and has been carefully corrected, according to the improved state of science. It also contains a Biography of Oliver Goldsmith, from the pen of WASHINGTON IRVING. This is the only edition that contains an unabridged Biography.

The publisher will feel obliged by his numerous subscribers comparing this edition with any other, and he has no doubt that the preference will be given to this ; which has been got up at an immense outlay, and will require an extensive sale before he becomes remunerated. He also hopes that the present subscribers will recommend the work to their circle of friends, and thus be the means of extending amusing and instructive knowledge, which is so desirable in the present state of society.

# CONTENTS.

---

## CHAP. I.

Birth and parentage...Characteristics of the Goldsmith race...Poetical birthplace...Goblin house...Scenes of boyhood...Lissoy...Picture of a country parson...Goldsmith's schoolmistress...Byrne, the village schoolmaster...Goldsmith's hornpipe and epigram...Uncle Contarine...School studies and sports...Mistakes of a night . . . . . 1

## BOOK I.

### ANIMALS OF THE HORSE KIND

CHAP. I.—The Horse	229
... II.—The Ass	239
... III.—The Zebra	243

## BOOK II.

### RUMINATING ANIMALS.

CHAP. I.—Introduction, 246.	
... II.—The Cow kind, 248; the Buffalo, 254.	
... III.—Animals of the Sheep and Goat kind, 257. The Sheep, 257; the Goat and its numerous varieties, 262; the Gazelle, 267.	
... IV.—The Musk Animal	273
... V.—Animals of the Deer kind, 275. The Fallow Deer, 284; the Roe-buck, 286; the Elk, 289; the Rein-deer, 294.	

## BOOK III.

### QUADRUPEDS OF THE HOG KIND.

CHAP. I.—Introduction, 298. The Wild Boar, 299; the Hog, 300.	
... II.—The Peccary or Tajacu	302
... III.—The Capibara or Cabiai	304
... IV.—The Babyrouessa, or Indian Hog	305

## BOOK IV.

### CARNIVOROUS ANIMALS.

CHAP. I.—Animals of the Cat kind, 307. The Lion, 311; the Tiger, 317; the Panther and the Leopard, 322.	
... II.—Animals of the Dog kind, 329. The Wolf, 339; the Fox, 345; the Jackal, 347; the Isatis, 350; the Hyæna, 350.	
... III.—Animals of the Weasel kind, 352. The Ermine, or Stoat, 354; the Ferret, 355; the Polecat, 357; the Martin, 358; the Sable, 360; the Ichneumon, 361; the Stinkards, 362; the Genet, 364; the Civet, 365; the Glutton, 367.	

## BOOK V.

### ANIMALS OF THE HARE KIND.

CHAP. I.—Introduction, 369. The Hare, 370; the Rabbit, 374; the Squirrel, 376; the Flying Squirrel, 379; the Marmout, 380; the Agouti, 384; the Paca, 385; the Guinea Pig, 386.	
---	--

BOOK VI.

ANIMALS OF THE RAT, HEDGEHOG, AND OTHER SIMILAR KINDS.

CHAP. I.—The Rat kind, 388. The Great Rat, 389; the Mouse, 391; the Dormouse, 392; the Musk Rat, 392; the Cricetus, 393; the Leming, 394; the Mole, 396.	
... II.—The Hedgehog or Prickly kind, 397. The Tanrec & Tendrac, 401; the Porcupine, 401.	
... III.—Quadrupeds covered with Scales or Shells instead of Hair, 404; the Pangolin, 405; the Armadillo, or Tatou, 406.	
... IV.—Animals of the Bat kind ...	409
... V.—Amphibious Quadrupeds, 413. The Otter, 414; the Beaver, 416; the Seal, 420; the Morse, 424; the Manati, 424.	

BOOK VII.

OF THE MONKEY KIND, AND OF THE ELEPHANT, THE RHINOCEROS, ETC.

CHAP. I.—Animals of the Monkey kind, 426. The Ouran Outang, 426; the Baboon, 432; the Monkey, 435; the Maki, 441; the Opossum and its kinds, 443.	
... II.—The Elephant ...	445
... III.—The Rhinoceros ...	456
... IV.—The Hippopotamos ...	458
... V.—The CAMELEOPARD ...	459
... VI.—The Camel and the Dromedary ...	460
... VII.—The Lama ...	463
... VIII.—The Nyl-gau ...	465
... IX.—The Bear ...	466
... X.—The Badger ...	468
... XI.—The Tapir ...	469
... XII.—The Raccoon ...	469
... XIII.—The Coatimondi ...	470
... XIV.—The Ant Bear ...	471
... XV.—The Sloth ...	472
... XVI.—The Gervua ...	474

PART IV.—BIRDS.

BOOK I.

OF BIRDS IN GENERAL.

CHAP. I.—Introduction ...	477
... II.—The Generation, Nesting, and Incubation of Birds ...	484
... III.—The Division of Birds ...	490
... IV.—The Ostrich ...	492
... V.—The Emu ...	497
... VI.—The Cassowary ...	498
... VII.—The Dodo ...	500

BOOK II.

RAPACIOUS BIRDS.

CHAP. I.—Rapacious Birds ...	501
... II.—The Eagle and its affinities ...	504
... III.—The Condor of America ...	507
... IV.—The Vulture and its affinities ...	509
... V.—The Falcon kind ...	513
... VI.—The Butcher-bird ...	517
... VII.—Rapacious Birds of the Owl kind that prey by night ...	519

BOOK III.

BIRDS OF THE POULTRY KIND.

CHAP. I.—Birds of the Poultry kind in general ...	523
... II.—The Cock ...	525

CHAP. III.—The Peacock ...	528
... IV.—The Turkey ...	530
... V.—The Pheasant ...	532
... VI.—The Pintada or Guinea-hen ...	534
... VII.—The Bustard ...	535
... VIII.—The Grouse and its affinities ...	536
... IX.—The Partridge and its affinities ...	538
... X.—The Quail ...	540

BOOK IV.

BIRDS OF THE PIE KIND.

CHAP. I.—Birds of the Pie kind in general ...	541
... II.—The Raven, the Crow, and their affinities ...	542
... III.—The Magpie and its affinities ...	546
... IV.—The Woodpecker and its affinities ...	550
... V.—The Bird of Paradise and its varieties ...	552
... VI.—The Cuckoo and its varieties ...	554
... VII.—The Parrot and its affinities ...	556
... VIII.—The Pigeon and its varieties ...	561

BOOK V.

BIRDS OF THE SPARROW KIND IN GENERAL.

CHAP. I.—Birds of the Sparrow kind ...	564
... II.—The Thrush and its affinities ...	571
... III.—The Nightingale and other soft-billed Song Birds ...	577

THE LARK FAMILY.

The Crested-lark; the Wood-lark; the Short-toed Lark; the Clapper-lark; the Red-backed Lark; the Double-crested Lark; Alpine-lark ...	581
---	-----

THE WARBLERS, CHATS, WAGTAILS, AND PIPITS.

... IV.—The Canary-bird and other hard-billed Singing Birds ...	583
... V.—The Swallow and its affinities ...	585
The House-sparrow; the Tree-sparrow; the Field-sparrow; the Song-sparrow; the Goldfinch; the Siskin-Goldwing; the Common-Goldwing; the Chaffinch; the Mountain-finch; the Yellow-hammer; the Reed-bunting; the Ortolan-bunting ...	588
... VI.—The Humming-bird and its varieties ...	589
The Hoopoe and the Creeper ...	591

BOOK VI.

BIRDS OF THE CRANE KIND.

CHAP. I.—Birds of the Crane kind in general ...	591
... II.—The Crane ...	593
... III.—The Stork ...	596
... IV.—Balearic and other Foreign Cranes ...	598
... V.—The Heron and its varieties ...	599
... VI.—The Bittern ...	602
... VII.—The Spoonbill ...	604
... VIII.—The Flamingo ...	605
... IX.—Avosetta and the Corivo ...	608
... X.—Small Birds of the Crane kind ...	609
... XI.—The Water-hen and the Coot ...	613

## BOOK VII.

## WATER-FOWL

CHAP. I.—Water-fowl in general	...	615
... II.—The Pelican	...	616
... III.—The Albatross	...	619
... IV.—The Cormorant	...	621
... V.—The Gannet	...	622
... VI.—Smaller Gulls and Petrels	...	624
... VII.—The Penguin kind	...	628
... VIII.—The Auk, the Puffin, and other birds of the Penguin kind	...	630
... IX.—Birds of the Goose kind	...	633
... X.—The Swan	...	635
... XI.—The Goose	...	637
... XII.—The Duck and its varieties	...	639
... XIII.—The Kingfisher	...	643

## PART V.—FISHES.

## BOOK I.

## FISHES IN GENERAL.

CHAP. I.—Introduction	...	647
... II.—Cetaceous Fishes in general	...	657
... III.—The Whale and its varieties	...	659
... IV.—The Narwhale	...	665
... V.—The Cachalot and its varieties	...	667
... VI.—The Dolphin—the Grampus—and the Porpoise, with their varieties	...	668

## BOOK II.

## CARTILAGINOUS FISHES.

CHAP. I.—Cartilaginous Fishes in general	...	670
... II.—Cartilaginous Fishes of the Shark kind	...	672
... III.—Cartilaginous Flat Fish of the Ray kind	...	676
... IV.—The Lamprey and its affinities	...	682
... V.—The Sturgeon and its affinities	...	684
... VI.—Anomalous Cartilaginous Fishes	...	687

## BOOK III.

## SPINOUS FISHES.

CHAP. I.—The Division of Spinous Fishes	...	690
Sec. I.—Prickly-finned Fishes	...	692
Sec. II.—Soft-finned Fishes	...	694
... II.—Spinous Fishes in general	...	696

## BOOK IV.

CHAP. I.—The Division of Shell-fish	...	707
... II.—Crustaceous Animals of the Lobster kind	...	708
... III.—The Tortoise and its kinds	...	715
... IV.—The Shell of Testaceous Fishes	...	723
... V.—Turbinated Shell-fish of the Snail kind	...	729
... VI.—Bivalved Shell-fish, or Shells of the Oyster kind	...	736
... VII.—Multivalve Shell-fish	...	741

## PART VI.—FROGS, &amp;c.

## BOOK I.

CHAP. I.—Frogs and Toads in general	...	745
... II.—The Frog and its varieties	...	751
... III.—The Toad and its varieties	...	751

## BOOK II.

CHAP. I.—Lizards in general	...	757
... II.—The Crocodile and its affinities	...	759

CHAP. III.—The Salamander	...	765
... IV.—The Cameleon, the Iguana, and Lizards of different kinds	...	768

## BOOK III.

CHAP. I.—Serpents in general	...	771
... II.—Venomous Serpents in general	...	782
... III.—Serpents without venom	...	789

## PART VII.—INSECTS.

## BOOK I.

## INSECTS OF THE FIRST ORDER.

CHAP. I.—Insects in general	...	794
... II.—Insects without Wings	...	797
... III.—The Spider and its varieties	...	798
... IV.—The Flea	...	804
... V.—The Louse and its varieties	...	808
... VI.—The Bug and its varieties	...	809
... VII.—The Woodlouse and its varieties	...	810
... VIII.—The Monoculus, or Aborescent Water-flea	...	811
... IX.—The Scorpion and its varieties	...	814
... X.—The Scolopendra and Gally-worm	...	815
... XI.—The Leech	...	815

## BOOK II.

## INSECTS OF THE SECOND ORDER.

CHAP. I.—The Second Order of Insects in general	...	817
... II.—The Libella, or Dragon-fly	...	819
... III.—The Formico Leo, or Lion-ant	...	822
... IV.—The Grasshopper, the Locust, the Cicada, the Cricket, and the Mole-cricket	...	829
... V.—The Earwig, the Froth Insect, and others belonging to the Second Order of Insects	...	831
... VI.—The Ephemera	...	831

## BOOK III.

## INSECTS OF THE THIRD ORDER.

CHAP. I.—Caterpillars in general	...	834
... II.—The Transformation of the Caterpillar into its corresponding Butterfly or Moth	...	835
... III.—Butterflies and Moths	...	842
... IV.—The Enemies of the Caterpillar	...	846
... V.—The Silkworm	...	848

## OLIVER GOLDSMITH.

### CHAP. I.

**Birth and parentage** Characteristics of the Goldsmith race—Poetical birthplace—Goblin house—Scenes of boyhood—Lissoy—Picture of a country parson—Goldsmith's school-mistress—Byrne, the village school-master—Goldsmith's hornpipe and epigram—Uncle Contarine—School studies and school sports—Mistakes of a night.

THERE are few writers for whom the reader feels such personal kindness as for Oliver Goldsmith, for few have so eminently possessed the magic gift of identifying themselves with their writings. We read his character in every page, and grow into familiar intimacy with him as we read. The artless benevolence that beams throughout his works—the whimsical but amiable views of human life and human nature—the unforced humour, blending so happily with good feeling and good sense, and singularly dashed at times with a pleasing melancholy—even the very nature of his mellow, and flowing, and softly-tinted style, all seem to bespeak his moral as well as his intellectual qualities, and make us love the man at the same time that we admire the author. While the productions of writers of loftier pretension and more sounding names are suffered to moulder on our shelves, those of Goldsmith are cherished and laid in our bosoms. We do not quote them with ostentation, but they mingle with our minds, sweeten our tempers, and harmonize our thoughts; they put us in good humour with ourselves and with the world, and in so doing they make us happier and better men.

An acquaintance with the private biography of Goldsmith lets us into the secret of his gifted pages. We there discover them to be little more than transcripts of his own heart and picturings of his fortune. There he shows himself the same kind, artless, good-humoured, excursive, sensible, whimsical, intelligent being that he appears in his writings. Scarcely an adventure or character is given in his works that may not be traced to his own parti-coloured story. Many of his most ludicrous scenes and ridiculous incidents have been drawn from his own blunders and mischances, and he seems really to have been buffeted into almost every maxim imparted by him for the instruction of his reader.

Oliver Goldsmith was born on the 10th of November, 1728, at the hamlet of Pallas, or Pallasmore, county of Longford, Ireland. He sprang from a respectable, but by no means a thrifty stock. Some families seem to inherit kindness and incompetency, and to hand down virtue and poverty from generation to generation. Such was the case with the Goldsmiths. "They were always," according to their own accounts, "a strange family; they rarely acted like other people; their hearts were in the right place, but their heads seemed to be doing anything but what they ought."—"They were remarkable," says another statement, "for their worth, but of no cleverness in the ways of the world." Oliver Goldsmith will be found faithfully to inherit the virtues and weaknesses of his race.

His father, the Rev. Charles Goldsmith, with hereditary improvidence, married when very young and very poor, and starved along for several years on a small country curacy and the assistance of his wife's friends.

His whole income, eked out by the produce of some fields which he farmed, and of some occasional duties performed for his wife's uncle, the rector of an adjoining parish, did not exceed forty pounds—

And passing rich with forty pounds a year.

He inhabited an old, half-rustic mansion, that stood on a rising ground in a rough lonely part of the country, overlooking a low tract occasionally flooded by the river Inny. In this house Goldsmith was born, and it was a birthplace worthy of a poet; for, by all accounts, it was haunted ground. A tradition handed down among the neighbouring peasantry states that, in after years, the house remaining for some time untenanted, went to decay, the roof fell in, and it became so lonely and forlorn as to be a resort for the "good people" or fairies, who in Ireland are supposed to delight in old crazy, deserted mansions for their midnight revels. All attempts to repair it were in vain; the fairies battled stoutly to maintain possession. A huge mis-shapen hobgoblin used to bestride the house every evening with an immense pair of jack-boots, which, in his efforts at hard riding, he would thrust through the roof, kicking to pieces all the work of the preceding day. The house was therefore left to its fate, and went to ruin.

Such is the popular tradition about Goldsmith's birthplace. About two years after his birth a change came over the circumstances of his father. By the death of his wife's uncle he succeeded to the rectory of Kilkenny West; and, abandoning the old goblin mansion, he removed to Lissoy, in the county of Westmeath, where he occupied a farm of seventy acres, situated on the skirts of that pretty village.

This was the scene of Goldsmith's boyhood—the little world whence he drew many of those pictures, rural and domestic, whimsical and touching, which abound throughout his works, and which appeal so eloquently both to the fancy and to the heart. Lissoy is confidently asserted as the original of his "Auburn" in the "Deserted Village;" his father's establishment, a mixture of farm and parsonage, furnished hints, it is said, for the rural economy of the Vicar of Wakefield; and his father himself, with his learned simplicity, his guileless wisdom, his amiable piety, and utter ignorance of the world, has been exquisitely portrayed in the worthy Dr. Primrose. Let us pause for a moment, and draw from Goldsmith's writings one or two of those pictures which, under feigned names, represent his father and his family, and the happy fireside of his childish days.

"My father," says the "Man in Black," who, in some respects, is a counterpart of Goldsmith himself, "my father, the younger son of a good family, was possessed of a small living in the church. His education was above his fortune, and his generosity greater than his education. Poor as he was, he had his flatterers poorer than himself: for every dinner he gave them they returned him an equivalent in praise; and this was all he wanted. The same ambition that actuates a monarch at the head of his army, influenced my father at the head of his table; he told the story of the ivy-tree, and that was laughed at; he repeated the jest of the two

scholars and one pair of breeches, and the company laughed at that; but the story of Taffy in the sedan-chair was sure to set the table in a roar. Thus his pleasure increased in proportion to the pleasure he gave; he loved all the world, and he fancied all the world loved him.

"As his fortune was but small, he lived up to the very extent of it: he had no intention of leaving his children money, for that was dross; he resolved they should have learning, for learning, he used to observe, was better than silver or gold. For this purpose he undertook to instruct us himself, and took as much care to form our morals as to improve our understanding. We were told that universal benevolence was what first cemented society: we were taught to consider all the wants of mankind as our own; to regard the *human face divine* with affection and esteem; he wound us up to be mere machines of pity, and rendered us incapable of withstanding the slightest impulse made either by real or fictitious distress. In a word, we were perfectly instructed in the art of giving away thousands before we were taught the necessary qualification of getting a farthing."

In the "Deserted Village" we have another picture of his father and his father's fireside:—

His house was known to all the vagrant train,  
He chid their wanderings, but relieved their pain;  
The long-remembered beggar was his guest,  
Whose beard, descending, swept his aged breast;  
The ruin'd spendthrift, now no longer proud,  
Claim'd kindred there, and had his claims allow'd;  
The broken soldier, kindly bade to stay,  
Sat by his fire, and talk'd the night away;  
Wept o'er his wounds, or tales of sorrow done,  
Shoulder'd his crutch, and show'd how fields were won.  
Pleased with his guest, the good man learn'd to glow,  
And quite forgot their vices in their woe;  
Careless their merits or their faults to scan,  
His pity gave ere charity began.

The family of the worthy pastor consisted of five sons and three daughters. Henry, the eldest, was the good man's pride and hope, and he tasked his slender means to the utmost in educating him for a learned and distinguished career. Oliver was the second son, and seven years younger than Henry, who was the guide and protector of his childhood, and to whom he was most tenderly attached throughout life.

Oliver's education began when he was about three years old; that is to say, he was gathered under the wings of one of those good old motherly dames, found in every village, who cluck together the whole callow brood of the neighbourhood, to teach them their letters and keep them out of harm's way. Mistress Elizabeth Delap, for that was her name, flourished in this capacity for upwards of fifty years, and it was the pride and the boast of her declining days, when nearly ninety years of age, that she was the first that had put a book (doubtless a hornbook) into Goldsmith's hands. Apparently he did not much profit by it, for she confessed he was one of the dullest boys she had ever dealt with, insomuch that she had sometimes doubted whether it was possible to make anything of him—a common case with imaginative children, who are apt to be beguiled from the dry abstractions of elementary study by the picturings of the fancy.

At six years of age he passed into the hands of the village schoolmaster, one Thomas (or, as he was commonly and irreverently named, Paddy) Byrne, a capital tutor for a poet. He had been educated for a pedagogue, but had enlisted in the army, served abroad during the wars of Queen Anne's time, and risen to the rank of quartermaster of a regiment in Spain. At the return of peace, having no longer exercise for the sword, he resumed the ferule, and drilled the urchin populace of Lissoy. Goldsmith is supposed to have had him and his school in view in the following sketch in his "Deserted Village":—

Beside yon straggling fence that skirts the way,  
With blossom'd furze unprofitably gay,  
There, in his noisy mansion, skill'd to rule,  
The village master taught his little school;  
A man severe he was, and stern to view—  
I knew him well, and every truant knew—  
Well had the boding tremblers learn'd to trace,  
The day's disasters in his morning face;  
Full well they laugh'd with counterfeited glee  
At all his jokes, for many a joke had he;  
Full well the busy whisper circling round,  
Convey'd the dismal tidings when he frown'd.  
Yet he was kind, or, if severe in aught,  
The love he bore to learning was in fault;  
The village all declared how much he knew—  
'Twas certain he could write and cipher too;  
Lands he could measure, terms and tides presage,  
And e'en the story ran that he could gauge:  
In arguing, too, the parson own'd his skill,  
For e'en though vanquish'd, he could argue still;  
While words of learned length and thund'ring sound  
Amaz'd the gazing rustics ranged around—  
And still they gaz'd, and still the wonder grew,  
That one small head should carry all he knew.

There are certain whimsical traits in the character of Byrne not given in the foregoing sketch. He was fond of talking of his vagabond wanderings in foreign lands, and had brought with him from the wars a world of campaigning stories, of which he was generally the hero, and which he could deal forth to his wondering scholars when he ought to have been teaching them their lessons. These travellers' tales had a powerful effect upon the vivid imagination of Goldsmith, and awakened an unconquerable passion for wandering and seeking adventure.

Byrne was, moreover, of a romantic vein, and exceedingly superstitious. He was deeply versed in the fairy superstitions which abound in Ireland, all which he professed implicitly to believe. Under his tuition Goldsmith soon became almost as great a proficient in fairy lore. From this branch of good-for-nothing knowledge his studies, by an easy transition, extended to the histories of robbers, pirates, smugglers, and the whole race of Irish rogues and rapparees. Everything, in short, that savoured of romance, fable, and adventure, was congenial to his poetic mind, and took instant root there; but the slow plants of useful knowledge were apt to be overrun, if not choked, by the weeds of his quick imagination.

Another trait of his motley preceptor, Byrne, was a disposition to dabble in poetry, and this likewise was caught by his pupil. Before he was eight years old Goldsmith had contracted a habit of scribbling verses on small scraps of paper, which, in a little while, he would throw into the fire. A few of these sybilline leaves, however, were rescued from the flames, and conveyed to his mother. The good woman read them with a mother's delight, and saw at once that her son was a genius and a poet. From that time she beset her husband with solicitations to give the boy an education suitable to his talents. The worthy man was already straightened by the costs of instruction of his eldest son Henry, and had intended to bring his second son up to a trade; but the mother would listen to no such thing; as usual her influence prevailed, and Oliver, instead of being instructed in some humble but cheerful and gainful handicraft, was devoted to poverty and the Muse.

A severe attack of the smallpox caused him to be taken from under the care of his story-telling preceptor, Byrne. His malady had nearly proved fatal, and his face remained pitted through life. On his recovery he was placed under the charge of the Rev. Mr. Griffin, schoolmaster of Elphin, in Roscommon, and became an inmate in the house of his uncle, John Goldsmith, Esq., of Ballyoughter, in that vicinity. He now entered upon studies of a high order, but without making any uncommon progress. Still a careless, easy facility of dis-

position, an amusing eccentricity of manners, and a vein of quiet and peculiar humour, rendered him a general favourite, and a trifling incident soon induced his uncle's family to concur in his mother's opinion of his genius.

A number of young folks had assembled at his uncle's to dance. One of the company, named Cummins, played on the violin. In the course of the evening Oliver undertook a hornpipe. His short and clumsy figure, and his face pitted and discoloured with the small-pox, rendered him a ludicrous figure in the eyes of the musician who made merry at his expense, dubbing him his little *Æsop*. Goldsmith was nettled by the jest, and, stopping short in the hornpipe, exclaimed—

Our herald hath proclaim'd this saying,  
See *Æsop* dancing, and his monkey playing.

The repartee was thought wonderful for a boy of nine years old, and Oliver became forthwith the wit and the bright genius of the family. It was thought a pity he should not receive the same advantages with his elder brother Henry, who had been sent to the university; and, as his father's circumstances would not afford it, several of his relatives, spurred on by the representations of his mother, agreed to contribute towards his expense. The greater part, however, was borne by his uncle, the Rev. Thomas Contarine. The worthy man had been the college companion of Bishop Berkeley, and was possessed of moderate means, holding the living of Carrick-on-Shannon. He had married the sister of Goldsmith's father, but was now a widower, with an only child, a daughter, named Jane. Contarine was a kind-hearted man, with a generosity beyond his means. He took Goldsmith into favour from his infancy: his house was open to him during the holidays; his daughter Jane, two years older than the poet, was his early playmate; and uncle Contarine continued to the last one of his most active, unwavering, and generous friends.

Fitted out in a great measure by this considerate relative, Oliver was now transferred to schools of a higher order, to prepare him for the university; first to one at Athlone, kept by the Rev. Mr. Campbell, and, at the end of two years, to one at Edgeworthstown, under the superintendence of the Rev. Patrick Hughes.

Even at these schools his proficiency does not appear to have been brilliant. He was indolent and careless, however, rather than dull, and, on the whole, appears to have been well thought of by his teachers. In his studies he inclined towards the Latin poets and historians; relished Ovid and Horace, and delighted in Livy. He exercised himself with pleasure in reading and translating Tacitus, and was brought to pay attention to style in his compositions by a reproof from his brother Henry, to whom he had written brief and confused letters, and who told him in reply, that if he had but little to say, to endeavour to say that little well.

The career of his brother Henry at the university was enough to stimulate him to exertion. He seemed to be realizing all his father's hopes, and was winning collegiate honours that the good man considered indicative of his future success in life.

In the meanwhile, Oliver, if not distinguished among his teachers, was popular among his schoolmates. He had a thoughtless generosity extremely captivating to young hearts: his temper was quick and sensitive, and easily offended; but his anger was momentary, and it was impossible for him to harbour resentment. He was the leader of all boyish sports and athletic amusements, especially ball-playing, and he was foremost in all mischievous pranks. Many years afterward, an old man, Jack Fitzsimmons, one of the directors of the sports and keeper of the ball-court at Ballymahon, used to boast of having been schoolmate of "Noll Goldsmith," as he called him, and would dwell with vain glory on one of their exploits, in robbing the orchard of Tirlicken, an old family residence of Lord Aunaly. The exploit, however, had nearly involved disastrous consequences; for the

crew of juvenile depredators were captured, like Shakespeare and his deer-stealing colleagues; and nothing but the respectability of Goldsmith's connexions saved him from the punishment that would have awaited more plebeian delinquents.

An amusing incident is related as occurring in Goldsmith's last journey homeward from Edgeworthstown. His father's house was about twenty miles distant; the road lay through a rough country, impassable for carriages. Goldsmith procured a horse for the journey, and a friend furnished him with a guinea for travelling expenses. He was but a stripling of sixteen, and being thus suddenly mounted on horseback, with money in his pocket, it is no wonder that his head was turned. He determined to play the man, and to spend his money in an independent traveller's style. Accordingly, instead of pushing directly for home, he halted for the night at the little town of Ardagh, and, accosting the first person he met, inquired, with somewhat of a consequential air, for the best house in the place. Unluckily, the person he had accosted was one Kelly, a notorious wag, who was quartered in the family of Mr. Featherstone, a gentleman of fortune. Amused with the self-consequence of the stripling, and willing to play off a practical joke at his expense, he directed him to what was literally "the best house in the place," namely, the family mansion of Mr. Featherstone. Goldsmith accordingly rode up to what he supposed to be an inn, ordered his horse to be taken to the stable, walked into the parlour, seated himself by the fire, and demanded what he could have for supper. On ordinary occasions he was diffident and even awkward in his manners, but here he was "at ease in his inn," and felt called upon to show his manhood, and enact the experienced traveller. His person was by no means calculated to play off his pretensions, for he was short and thick, with a pock-marked face, and an air of carriage by no means of a distinguished cast. The owner of the house, however, soon discovered his whimsical mistake, and, being a man of humour, determined to indulge it, especially as he accidentally learned that this intruding guest was the son of an old acquaintance.

Accordingly, Goldsmith was "fooled to the top of his bent," and permitted to have full sway throughout the evening. Never was schoolboy more elated. When supper was served, he most condescendingly insisted that the landlord, his wife, and daughter, should partake, and ordered a bottle of wine to crown the repast and benefit the house. His last flourish was on going to bed, when he gave especial orders to have a hot cake at breakfast. His confusion and dismay, on discovering the next morning that he had been swaggering in this free and easy way in the house of a private gentleman, may be readily conceived. True to the habit of turning the events of his life to literary account, we find this chapter of ludicrous blunders and cross purposes dramatized many years afterward in his admirable comedy of "She Stoops to Conquer, or the Mistakes of a Night."

## CHAP. II.

Improvident marriages in the Goldsmith family—Goldsmith at the university—Situation of a Sizer—Tyranny of Wilder, the tutor—Pecuniary straits—Street ballads—College riot—Gallows Walsh—College prize—A dance interrupted.

While Oliver was making his way somewhat negligently through the schools, his elder brother Henry was rejoicing his father's heart by his career at the University. He soon distinguished himself at the examinations, and obtained a scholarship in 1743. This is a collegiate distinction which serves as a stepping-stone in any of the learned professions, and which leads to advancement in the University should the individual

choose to remain there. His father now trusted that he would push forward for that comfortable provision, a fellowship, and thence to higher dignities and emoluments. Henry, however, had the providence or the "unworldliness" of his race: returning to the country during the succeeding vacation, he married for love, relinquished, of course, all his collegiate prospects and advantages, set up a school in his father's neighbourhood, and buried his talents and acquirements for the remainder of his life in a curacy of forty pounds a year.

Another matrimonial event occurred not long afterwards in the Goldsmith family, to disturb the equanimity of its worthy head. This was the clandestine marriage of his daughter Catherine with a young gentleman of the name of Hodson, who had been confided to the care of her brother Henry to complete his studies. As the youth was of wealthy parentage, it was thought a lucky match for the Goldsmith family; but the tidings of the event stung the bride's father to the soul. Proud of his integrity, and jealous of that good name which was his chief possession, he saw himself and his family subjected to the degrading suspicion of having abused a trust reposed in them to promote a mercenary match. In the first transports of his feelings, he is said to have uttered a wish that his daughter might never have a child to bring like shame and sorrow on her head. The hasty wish, so contrary to the usual benignity of the man, was recalled and repented of almost as soon as uttered; but it was considered baleful in its effects by the superstitious neighbourhood; for, though his daughter bore three children, they all died before her.

A more effectual measure was taken by Mr. Goldsmith to ward off the apprehended imputation, but one which imposed a heavy burden on his family. This was to furnish a marriage portion of four hundred pounds, that his daughter might not be said to have entered her husband's family empty-handed. To raise the sum in cash was impossible; but he assigned to Mr. Hodson his little farm and the income of his tithes until the marriage portion should be paid. In the meantime, as his living did not amount to £200 per annum, he had to practise the strictest economy to pay off gradually this heavy tax incurred by his nice sense of honour.

The first of his family to feel the effects of this economy was Oliver. The time had now arrived for him to be sent to the university; and, accordingly, on the 11th June, 1747, when sixteen years of age, he entered Trinity College, Dublin; but his father was no longer able to place him there as a pensioner, as he had done his eldest son Henry; he was obliged, therefore, to enter him as a "sizer," or poor scholar. He was lodged in one of the top rooms adjoining a library of the building, numbered 35, where it is said his name may still be seen, scratched by himself upon a window-frame.

A student of this class is taught and boarded gratuitously, and has to pay a very small sum for his room. It is expected, in return for these advantages, that he will be a diligent student, and render himself useful in a variety of ways. In Trinity College, at the time of Goldsmith's admission, several derogatory, and, indeed, menial, offices were exacted from the sizer, as if the college sought to indemnify itself for conferring benefits by inflicting indignities. He was obliged to sweep part of the courts in the morning—to carry up the dishes from the kitchen to the fellows' table, and to wait in the hall till that body had dined. His very dress marked the inferiority of the "poor student" to his happier classmates. It was a black gown of coarse stuff without sleeves, and a plain black cloth cap without a tassel. We can conceive nothing more odious and ill-judged than these distinctions, which attached the idea of degradation to poverty, and placed the indigent youth of merit below the worthless minion of fortune. They were calculated to wound and irritate the noble mind, and to render the base mind baser.

Indeed, the galling effect of these servile tasks upon youths of proud spirits and quick sensibilities became at length too notorious to be disregarded. About fifty years since, on a Trinity Sunday, a number of persons were assembled to witness the college ceremonies; and as a sizer was carrying up a dish of meat to the fellows' table, a burly citizen in the crowd made some sneering observations on the servility of his office. Stung to the quick, the high-spirited youth instantly flung the dish and its contents at the head of the sneerer. The sizer was sharply reprimanded for this outbreak of wounded pride, but the degrading task was from that day forward very properly consigned to menial hands.

It was with the utmost repugnance that Goldsmith entered college in this capacity. His shy and sensitive nature was affected by the inferior station he was doomed to hold among his gay and opulent fellow-students, and he became at times moody and despondent. A recollection of these early mortifications induced him in after years most strongly to dissuade his brother Henry, the clergyman, from sending a son to college on a like footing. "If he has ambition, strong passions, and an exquisite sensibility of contempt, do not send him there, unless you have no other trade for him except your own."

To add to his annoyances, the fellow of the college who had the peculiar control of his studies, the Rev. Theaker Wilder, was a man of violent and capricious temper, and of diametrically opposite tastes. The tutor was devoted to the exact sciences—Goldsmith was for the classics. Wilder endeavoured to force his favourite studies upon the student by harsh means, suggested by his own coarse and savage nature. He abused him in presence of the class as ignorant and stupid; ridiculed him as awkward and ugly, and at times in the transports of his temper indulged in personal violence. The effect was to aggravate a passive distaste into a positive aversion. Goldsmith was loud in expressing his contempt for mathematics and his dislike for ethics and logic; and the prejudices thus imbibed continued through life. Mathematics he always pronounced a science to which the meanest intellects were competent.

A truer cause of this distaste for the severer studies may probably be found in his natural indolence and his love of convivial pleasures. I was a lover of mirth, good-humour, and even sometimes of fun," said he, "from my childhood." He sang a good song, was a boon companion, and could not resist any temptation to social enjoyment. He endeavoured to persuade himself that learning and dullness went hand in hand, and that genius was not to be put in harness. Even in riper years, when the consciousness of his own deficiencies ought to have convinced him of the importance of early study, he speaks slightly of college honours.

"A lad," says he, "whose passions are not strong enough in youth to mislead him from that path of science which his tutors and not his inclination have chalked out, by four or five years' perseverance will probably obtain every advantage and honour his college can bestow. I would compare the man whose youth has been thus passed in the tranquillity of dispassionate prudence to liquors that never ferment, and, consequently, continue always muddy."

The death of his worthy father, which took place early in 1747, rendered Goldsmith's situation at college extremely irksome. His mother was left with little more than the means of providing for the wants of her household, and was unable to furnish him any remittances. He would have been compelled, therefore, to leave college, had it not been for the occasional contributions of friends, the foremost among whom was his generous and warm-hearted uncle Contarine. Still these supplies were so scanty and precarious, that in the intervals between them he was put to great straits. He had two college associates from whom he would occa-

sionally borrow small sums; one was an early school-mate, by the name of Beatty; the other a cousin, and a chosen companion of his frolics, Robert (or rather Bob) Bryanton, of Ballymulvey House, near Ballymahon. When these casual supplies failed him, he was more than once obliged to raise funds for his immediate wants by pawning his books. At times he sank into despondency, but he had what he termed "a knack at hoping," which soon buoyed him up again. He began now to resort to his poetical vein as a source of profit, scribbling street-ballads, which he privately sold for five shillings each at a shop which dealt in such small wares of literature. He felt an author's affection for these unowned bantlings, and we are told would stroll privately through the streets at night to hear them sung, listening to the comments and criticisms of by-standers, and observing the degree of applause which each received.

Edmund Burke was a fellow-student with Goldsmith at the college. Neither the statesman nor the poet gave promise of their future celebrity, though Burke certainly surpassed his contemporary in industry and application, and evinced more disposition for self-improvement, associating himself with a number of his fellow-students in a debating-club, in which they discussed literary topics, and exercised themselves in composition.

Goldsmith may likewise have belonged to this association, but his propensity was rather to mingle with the gay and thoughtless. On one occasion we find him implicated in an affair that came nigh producing his expulsion. A report was brought to college that a scholar was in the hands of the bailiffs. This was an insult in which every gownsmen felt himself involved. A number of the scholars flew to arms, and sallied forth to battle, headed by a hair-brained fellow named Gallows Walsh, noted for his aptness at mischief and fondness for riot. The stronghold of the bailiff was carried by storm, the scholar set at liberty, and the delinquent catchpole borne off captive to the college, where, having no pump to put him under, they satisfied the demands of collegiate law by ducking him in an old cistern.

Flushed with this signal victory, Gallows Walsh now harangued his followers, and proposed to break open Newgate, or the Black Dog, as the prison was called, and effect a general jail-delivery. He was answered by shouts of concurrence, and away went the throng of madcap youngsters fully bent upon putting an end to the tyranny of law. They were joined by the mob of the city, and made an attack upon the prison with true Irish precipitation and thoughtlessness, never having provided themselves with cannon to batter its stone walls. A few shots from the prison brought them to their senses, and they beat a hasty retreat, two of the townsmen being killed, and several wounded.

A severe scrutiny of this affair took place at the university. Four students, who had been ringleaders, were expelled; four others who had been prominent in the affray, were publicly admonished; among the latter was the unlucky Goldsmith.

To make up for this disgrace, he gained, within a month afterward, one of the minor prizes of the college. It is true it was one of the very smallest, amounting in pecuniary value to but thirty shillings, but it was the first distinction he had gained in his whole collegiate career. This turn of success and sudden influx of wealth proved too much for the head of our poor student. He forthwith gave a supper and dance at his chamber to a number of young persons of both sexes from the city, in direct violation of college rules. The unwonted sound of the fiddle reached the ears of the implacable Wilder. He rushed to the scene of unhallowed festivity, inflicted corporeal punishment on the "father of the feast," and turned his astonished guests neck and heels out of doors.

This filled the measure of poor Goldsmith's humiliations; he felt degraded both within college and without.

He dreaded the ridicule of his fellow-students for the ludicrous termination of his orgie, and he was ashamed to meet his city acquaintances after the degrading chastisement received in their presence, and after their own ignominious expulsion. Above all, he felt it impossible to submit to the insulting tyranny of Wilder: he determined, therefore, to leave, not merely the college, but also his native land, and to bury what he conceived to be his irretrievable disgrace in some distant country. He accordingly sold his books and clothes, and sallied forth from the college walls the very next day, intending to embark at Cork for—he scarce knew where—America, or any other part beyond sea. With his usual imprudence, however, he loitered about Dublin until his finances were reduced to a shilling; with this amount of specie he set out on his journey.

For three whole days he subsisted on his shilling; when that was spent, he parted with some of the clothes from his back, until, reduced almost to nakedness, he was four-and-twenty hours without food, inasmuch that he declared a handful of grey peas, given to him by a girl at a wake, was one of the most delicious repasts he had ever tasted. Hunger, fatigue, and destitution brought down his spirit and calmed his anger. Fain would he have retraced his steps, could he have done so with any salvo for the lingerings of his pride. In this extremity he conveyed to his brother Henry information of his distress, and of the rash project on which he had set out. His affectionate brother hastened to his relief; furnished him with money and clothes; soothed his feelings with gentle counsel; prevailed upon him to return to college, and effected an indifferent reconciliation between him and Wilder.

After this irregular sally upon life he remained nearly two years longer at the university, giving proofs of talent in occasional translations from the classics, for one of which he received a premium, awarded only to those who are the first in literary merit. Still he never made much figure at college, his natural disinclination to study being increased by the harsh treatment he continued to experience from his tutor.

Among the anecdotes told of him while at college is one indicative of that prompt but thoughtless and often whimsical benevolence which throughout life formed one of the most eccentric, yet endearing points of his character. He was engaged to breakfast one day with a college intimate, but failed to make his appearance. His friend repaired to his room, knocked at the door, and was bidden to enter. To his surprise he found Goldsmith in bed, immersed to his chin in feathers. A serio-comic story explained the circumstance. In the course of the preceding evening's stroll he had met with a woman with five children, who implored his charity. Her husband was in the hospital; she was just from the country, a stranger, and destitute, without food or shelter for her helpless offspring. This was too much for the kind heart of Goldsmith. He was almost as poor as herself, it is true, and had no money in his pocket; but he brought her to the college gate, gave her the blankets from his bed to cover her little brood, and part of his clothes for her to sell and purchase food; and, finding himself cold during the night, had cut open his bed and buried himself among the feathers.

At length, on the 27th of February, 1749, O. S., he was admitted to the degree of Bachelor of Arts, and took his final leave of the university. He was freed from college rule—that emancipation so ardently coveted by the thoughtless student, and which too generally launches him amid the cares, the hardships, and vicissitudes of life. He was freed, too, from the brutal tyranny of Wilder. If his kind and placable nature could retain any resentment for past injuries, it might have been gratified by learning subsequently that the passionate career of Wilder was terminated by a violent death in the course of a dissolute brawl; but Goldsmith

took no delight in the misfortunes even of his enemies.

He now returned to his friends, no longer the student to sport away the happy interval of vacation, but the anxious man, who is henceforth to shift for himself and make his way through the world. In fact, he had no legitimate home to return to. At the death of his father, the paternal house at Lissoy, in which Goldsmith had passed his childhood, had been taken by Mr. Hodson, who had married his sister Catherine. His mother had removed to Ballymahon, where she occupied a small house, and had to practise the severest frugality. His elder brother Henry served the curacy and taught the school of his late father's parish, and lived in narrow circumstances at Goldsmith's birthplace, the old goblin-house at Pallas.

None of his relatives were in circumstances to aid him with anything more than a temporary home, and the aspect of every one seemed somewhat changed. In fact, his career at college had disappointed his friends, and they began to doubt his being the great genius they had fancied him. He whimsically alludes to this circumstance in that piece of autobiography, "The Man in Black," in the "Citizen of the World."

"The first opportunity my father had of finding his expectations disappointed was in the middling figure I made at the university: he had flattered himself that he should soon see me rising into the foremost rank in literary reputation, but was mortified to find me utterly unnoticed and unknown. His disappointment might have been partly ascribed to his having overrated my talents, and partly to my dislike of mathematical reasonings at a time when my imagination and memory, yet unsatisfied, were more eager after new objects than desirous of reasoning upon those I knew. This, however, did not please my tutors, who observed, indeed, that I was a little dull, but at the same time allowed that I seemed to be very goodnatured, and had no harm in me."

The only one of his relatives who did not appear to lose faith in him was his uncle Contarine. This kind and considerate man, it is said, saw in him a warmth of heart requiring some skill to direct, and a latent genius that wanted time to mature, and these impressions none of his subsequent follies and irregularities wholly obliterated. His purse and affection, therefore, as well as his house, were now open to him, and he became his chief counsellor and director after his father's death. He urged him to prepare for holy orders; and others of his relatives concurred in the advice. Goldsmith had a settled repugnance to a clerical life. This has been ascribed by some to conscientious scruples, not considering himself of a temper and frame of mind for such a sacred office: others attributed it to his roving propensities, and his desire to visit foreign countries; he himself gives a whimsical objection in his biography of the "Man in Black":—"To be obliged to wear a long wig when I liked a short one, or a black coat when I generally dressed in brown, I thought such a restraint upon my liberty that I absolutely rejected the proposal."

In effect, however, his scruples were overruled, and he agreed to qualify himself for the office. He was now only twenty-one, and must pass two years of probation. They were two years of rather loitering, unsettled life. Sometimes he was at Lissoy, participating with thoughtless enjoyment in the rural sports and occupations of his brother-in-law, Mr. Hodson; sometimes he was with his brother Henry, at the old goblin mansion at Pallas, assisting him occasionally in his school. The early marriage and unambitious retirement of Henry, though so subversive of the fond plans of his father, had proved happy in their results. He was already surrounded by a blooming family; he was contented with his lot, beloved by his parishioners, and lived in the daily practice of all the amiable virtues, and the immediate enjoyment of their reward. Of the tender affection inspired in the breast of Goldsmith by the constant

kindness of this excellent brother, and of the longing recollection with which, in the lonely wanderings of after years, he looked back upon this scene of domestic felicity, we have a touching instance in the well-known opening to his poem of "The Traveller":—

Remote, unfriended, melancholy, slow,  
Or by the lazy Scheld or wandering Po;

Where'er I roam, whatever realms to see,  
My heart untravell'd fondly turns to thee;  
Still to my brother turns with ceaseless pain,  
And drags at each remove a lengthening chain.  
Eternal blessings crown my earliest friend,  
And round his dwelling guardian saints attend:  
Bless'd be that spot, where cheerful guests retire  
To pause from toil, and trim their evening fire;  
Bless'd that abode, where want and pain repair,  
And every stranger finds a ready chair:  
Bless'd be those feasts with simple plenty crown'd,  
Where all the ruddy family around  
Laugh at the jests or pranks that never fail,  
Or sigh with pity at some mournful tale;  
Or press the bashful stranger to his food,  
And learn the luxury of doing good.

During this loitering life Goldsmith pursued no study, but rather amused himself with miscellaneous reading; such as biography, travels, poetry, novels, plays—everything, in short, that administered to the imagination. Sometimes he strolled along the banks of the river Inny; where in after years, when he had become famous, his favourite seats and haunts used to be pointed out. Often he joined in the rustic sports of the villagers, and became adroit at throwing the sledge, a favourite feat of activity and strength in Ireland. Recollections of these "healthful sports" we find in his "Deserted Village":—

How often have I bless'd the coming day,  
When toil remitting lent its turn to play,  
And all the village train, from labour free,  
Led up their sports beneath the spreading tree;  
And many a gambol frolick'd o'er the ground,  
And sleights of art and feats of strength went round.

A boon companion in all his rural amusements was his cousin and college crony, Robert Bryanton, with whom he sojourned occasionally at Ballymulvey House in the neighbourhood. They used to make excursions about the country on foot, sometimes fishing, sometimes hunting otter in the Inny. They got up a country club at the little inn of Ballymahon, of which Goldsmith soon became the oracle and prime wit; astonishing his unlettered associates by his learning, and being considered capital at a song and a story. From the rustic conviviality of the inn at Ballymahon, and the company which used to assemble there, it is surmised that he took some hints in after life for his picturing of Tony Lumpkin and his associates: "Dick Muggins, the exciseman; Jack Slang, the horse doctor; little Aminadab, that grinds the music box, and Tom Twist, that spins the pewter platter." Nay, it is thought that Tony's drinking song at the "Three Jolly Pigeons," was but a revival of one of the convivial catches at Ballymahon:—

Then come, put the jorum about,  
And let us be merry and clever,  
Our hearts and our liquors are stout,  
Here's the Three Jolly Pigeons for ever.  
Let some cry of woodcock or hare,  
Your bustards, your ducks, and your widgeons,  
But of all the gay birds in the air,  
Here's health to the Three Jolly Pigeons.  
Toroddle, toroddle, toroll.

Notwithstanding all these accomplishments and this rural popularity, his friends began to shake their heads and shrug their shoulders when they spoke of him; and his brother Henry noted with anything but satisfaction his frequent visits to the club at Ballymahon. He emerged, however, unscathed from this dangerous ordeal, more fortunate in this respect than his comrade Bryanton; but he retained throughout life a fondness for clubs: often, too, in the course of his chequered career, he looked back to this period of rural sports and careless

enjoyments, as one of the few sunny sports of his cloudy life; and though he ultimately rose to associate with birds of a finer feather, his heart would still yearn in secret after the "Three Jolly Pigeons."

### CHAP. III.

*Goldsmitb rejected by the Bishop—Second sally to see the world—Takes passage for America—Ship sails without him—Return on Fiddle-back—A hospitable friend—The Counsellor.*

The time was now arrived for Goldsmith to apply for orders, and he presented himself accordingly before the Bishop of Elfin for ordination. We have stated his great objection to clerical life, the obligation to wear a black coat; and whimsical as it may appear, dress seems in fact to have formed an obstacle to his entrance into the church. He had ever a passion for clothing his sturdy but awkward little person in gay colours; and on this solemn occasion, when it was to be supposed his garb would be of suitable gravity, he appeared luminously arrayed in scarlet breeches! He was rejected by the bishop: some say for want of sufficient studious preparation—his rambles and frolics with Bob Bryant, and his revels with the club at Ballymahon, having been much in the way of his theological studies; others attribute his rejection to reports of his college irregularities, which the bishop had received from his old tyrant Wilder; but those who look into the matter with more knowing eyes, pronounce the scarlet breeches to have been the fundamental objection. "My friends," says Goldsmith, speaking through his humorous representative, the "Man in Black"—"my friends were now perfectly satisfied I was undone; and yet they thought it a pity for one that had not the least harm in him, and was so very good-natured." His uncle Contarine, however, still remained unwavering in his kindness, though much less sanguine in his expectations. He now looked round for a humbler sphere of action, and through his influence and exertions Oliver was received as tutor in the family of a Mr. Flinn, a gentleman of the neighbourhood. The situation was apparently respectable; he had his seat at the table, and joined the family in their domestic recreations and their evening game at cards. There was a servility, however, in his position, which was not to his taste: nor did his deference for the family increase upon familiar intercourse. He charged a member of it with unfair play at cards. A violent altercation ensued, which ended in his throwing up his situation as tutor. On being paid off he found himself in possession of an unheard-of amount of money. His wandering propensity and his desire to see the world were instantly in the ascendency. Without communicating his plans or his intentions to his friends, he procured a good horse, and with thirty pounds in his pocket made his second sally forth into the world.

The worthy niece and housekeeper of the hero of *La Mancha* could not have been more surprised and dismayed at one of the Don's clandestine expeditions, than were the mother and friends of Goldsmith when they heard of his mysterious departure. Weeks elapsed, and nothing was seen or heard of him. It was feared that he had left the country on one of his wandering freaks, and his poor mother was reduced almost to despair, when one day he arrived at her door almost as forlorn in plight as the prodigal son. Of his thirty pounds not a shilling was left; and instead of the goodly steed on which he had issued forth on his errantry, he was mounted on a sorry little pony, which he had nicknamed Fiddle-back. As soon as his mother was well assured of his safety, she rated him soundly for his inconsiderate conduct. His brothers and sisters, who were tenderly

attached to him, interfered, and succeeded in mollifying her ire; and whatever lurking anger the good dame might have, was no doubt effectually vanquished by the following whimsical narrative, which he drew up at his brother's house and despatched to her.

"My dear mother, if you will sit down and calmly listen to what I say, you shall be fully resolved in every one of those many questions you have asked me. I went to Cork, and converted my horse, which you prize so much higher than Fiddle-back, into cash, took my passage in a ship bound for America, and, at the same time, paid the captain for my freight and all the other expenses of my voyage. But it so happened the wind did not answer for three weeks; and you know, mother, that I could not command the elements. My misfortune was, that, when the wind served, I happened to be with a party in the country, and my friend the captain never inquired after me, but set sail with as much indifference as if I had been on board. The remainder of the time I employed in the city and its environs, viewing everything curious, and you know no one can starve while he has money in his pocket.

"Reduced, however, to my last two guineas, I began to think of my dear mother and friends whom I had left behind me, and so bought that generous beast Fiddle-back, and bade adieu to Cork with only five shillings in my pocket. This, to be sure, was but a scanty allowance for man and horse towards a journey of above a hundred miles; but I did not despair, for I knew I must find friends on the road.

"I recollected particularly an old and faithful acquaintance I made at college, who had often and earnestly pressed me to spend a summer with him, and he lived but eight miles from Cork. This circumstance of vicinity he would expatiate on to me with peculiar emphasis. 'We shall,' says he, 'enjoy the delights of both city and country, and you shall command my stable and my purse.'

"However, upon the way I met a poor woman all in tears, who told me her husband had been arrested for a debt he was not able to pay, and that his eight children must now starve, bereaved as they were of his industry, which had been their only support. I thought myself at home, being not far from my good friend's house, and therefore parted with a moiety of all my store; and pray, mother, ought I not to have given her the other half-crown, for what she got would be of little use to her? However, I soon arrived at the mansion of my affectionate friend, guarded by the vigilance of a huge mastiff, who flew at me and would have torn me to pieces but for the assistance of a woman, whose countenance was not less grim than that of the dog; yet she with great humanity relieved me from the jaws of this Cerberus, and was prevailed on to carry up my name to her master.

"Without suffering me to wait long, my old friend, who was then recovering from a severe fit of sickness, came down in his nightcap, nightgown, and slippers, and embraced me with the most cordial welcome, showed me in, and, after giving me a history of his indisposition, assured me that he considered himself peculiarly fortunate in having under his roof the man he most loved on earth, and whose stay with him must, above all things, contribute to his perfect recovery. I now repented sorely I had not given the poor woman the other half-crown, as I thought all my bills of humanity would be punctually answered by this worthy man. I revealed to him my whole soul; I opened to him all my distresses; and freely owned that I had but one half-crown in my pocket; but that now, like a ship after weathering out the storm, I considered myself secure in a safe and hospitable harbour. He made no answer, but walked about the room, rubbing his hands as one in deep study. This I imputed to the sympathetic feelings of a tender heart, which increased my esteem for him, and, as that

increased, I gave the most favourable interpretation to his silence. I construed it into delicacy of sentiment, as if he dreaded to wound my pride by expressing his commiseration in words, leaving his generous conduct to speak for itself.

"It now approached six o'clock in the evening, and as I had eaten no breakfast, and as my spirits were raised, my appetite for dinner grew uncommonly keen. At length the old woman came into the room with two plates, one spoon, and a dirty cloth, which she laid upon the table. This appearance, without increasing my spirits, did not diminish my appetite. My protectress soon returned with a small bowl of sago, a small porringer of sour milk, a loaf of stale brown bread, and the heel of an old cheese all over crawling with mites. My friend apologised that his illness obliged him to live on slops, and that better fare was not in the house; observing, at the same time, that a milk diet was certainly the most healthful; and at eight o'clock he again recommended a regular life, declaring for his part he would 'lie down with the lamb and rise with the lark.' My hunger was at this time so exceedingly sharp that I wished for another slice of the loaf, but was obliged to go to bed without even that refreshment.

"This lenten entertainment I had received made me resolve to depart as soon as possible; accordingly, next morning, when I spoke of going, he did not oppose my resolution; he rather commended my design, adding some very sage counsel upon the occasion. 'To be sure,' said he, 'the longer you stay away from your mother the more you will grieve her and your other friends; and possibly they are already afflicted at hearing of this foolish expedition you have made.' Notwithstanding all this, and without any hope of softening such a sordid heart, I again renewed the tale of my distress, and asking 'how he thought I could travel above a hundred miles upon one half-crown?' I begged to borrow a single guinea, which I assured him should be repaid with thanks. 'And you know, sir,' said I, 'it is no more than I have done for you.' To which he firmly answered, 'Why, look you, Mr. Goldsmith, that is neither here nor there. I have paid you all you ever lent me, and this sickness of mine has left me bare of cash. But I have bethought myself of a conveyance for you; sell your horse, and I will furnish you a much better one to ride on. I readily grasped at his proposal, and begged to see the nag; on which he led me to his bed-chamber, and from under the bed he pulled out a stout oak stick. 'Here he is,' said he; 'take this in your hand, and it will carry you to your mother's with more safety than such a horse as you ride.' I was in doubt, when I got it into my head, whether I should not in the first place apply it to his pate; but a rap at the street door made the wretch fly to it, and when I returned to the parlour he introduced me, as if nothing of the kind had happened, to the gentleman who entered, as Mr. Goldsmith, his most ingenious and worthy friend, of whom he had so often heard him speak with rapture. I could scarcely compose myself; and must have betrayed indignation in my mien to the stranger, who was a counsellor-at-law in the neighbourhood, a man of engaging aspect and polite address.

"After spending an hour, he asked my friend and me to dine with him at his house. This I declined at first, as I wished to have no further communication with my hospitable friend; but at the solicitation of both I at last consented, determined as I was by two motives; one, that I was prejudiced in favour of the looks and manner of the counsellor; and the other, that I stood in need of a comfortable dinner. And there, indeed, I found everything I could wish, abundance without profusion, and elegance without affectation. In the evening, when my old friend, who had eaten very plentifully at his neighbour's table, but talked again of lying down with the lamb, made a motion to me for retiring, our

generous host requested I should take a bed with him, upon which I plainly told my old friend that he might go home and take care of the horse he had given me, but that I should never re-enter his doors. He went away with a laugh, leaving me to add this to the other little things the counsellor already knew of his plausible neighbour.

"And now, my dear mother, I found sufficient to reconcile me to all my follies; for here I spent three whole days. The counsellor had two sweet girls to his daughters, who played enchantingly on the harpsichord; and yet it was but a melancholy pleasure I felt the first time I heard them; for that being the first time also that either of them had touched the instrument since their mother's death, I saw the tears in silence trickle down their father's cheeks. I every day endeavoured to go away, but every day was pressed and obliged to stay. On my going, the counsellor offered me his purse, with a horse and servant to convey me home; but the latter I declined, and only took a guinea to bear my necessary expenses on the road.

"OLIVER GOLDSMITH.

"To Mrs. Anne Goldsmith, Ballymahon."

Such is the story given by the poet-errant of this his second sally in quest of adventures. We cannot but think it was here and there touched up a little with the fanciful pen of the future essayist, with a view to amuse his mother and soften her vexation; but even in these respects it is valuable, as showing the early play of his humour, and his happy knack of extracting sweets from that worldly experience which to others yields nothing but bitterness.

#### CHAP. IV.

Sallies forth as a law student—Stumbles at the outset—Cousin Jane and the valentine—A family oracle—Sallies forth as a student of medicine—Hocus-pocus of a boarding-house—Transformation of a leg of mutton—The mock ghost—Sketches of Scotland—Trials of toadyism—A poet's purse for a continental tour.

A new consultation was held among Goldsmith's friends as to his future course, and it was determined he should try the law. His uncle Contarine agreed to advance the necessary funds, and actually furnished him with fifty pounds, with which he set off for London to enter on his studies at the Temple. Unfortunately, he fell in company at Dublin with a Roscommon acquaintance, one whose wits had been sharpened about town, who beguiled him into a gambling-house, and soon left him as penniless as when he bestrode the redoubtable Fiddle-back.

He was so ashamed of this fresh instance of gross heedlessness and imprudence, that he remained some time in Dublin without communicating to his friends his destitute condition. They heard of it, however, and he was invited back to the country, and indulgently forgiven by his generous uncle, but less readily by his mother, who was mortified and disheartened at seeing all her early hopes of him so repeatedly blighted. His brother Henry, too, began to lose patience at these successive failures, resulting from thoughtless indiscretion; and a quarrel took place, which for some time interrupted their usually affectionate intercourse.

The only home where poor erring Goldsmith still received a welcome was the parsonage of his affectionate and forgiving uncle. Here he used to talk of literature with the good simple-hearted man, and delight him and his daughter with his verses. Jane, his early playmate, was now "the woman grown;" their intercourse was of poetry and music; she played on the harpsichord, and he accompanied her with his flute. The music may not have been very artistic, as he never performed but by ear; it had probably as much merit as the poetry, which,

if we may judge by the following specimen, was as yet but juvenile:—

*"To a Young Lady on Valentine's-day, with the drawing of a heart."*

With submission at your shrine,  
Comes a heart your Valentine,  
From the side where once it grew,  
See, it panting flies to you.  
Take it, fair one, to your breast,  
Soothe the fluttering thing to rest;  
Let the gentle, spotless toy  
Be your sweetest, greatest joy;  
Every night, when wrapp'd in sleep,  
Next your heart the conquest keep;  
Or if dreams your fancy move,  
Hear it whisper me in love.  
Then in pity to the swain,  
Who must heartless else remain,  
Soft as gentle, dewy flows  
Slow descend on April flows—  
Soft as gentle riv'lets glide,  
Steal unnoticed to my side;  
If the gem you have to spare,  
Take your own and place it there."

If this valentine was intended for the fair Jane, and expressive of a tender sentiment indulged by the strippling poet, it was unavailing; as not long afterwards she was married to a Mr. Lawder. We trust, however, it was but a poetical passion of that transient kind which grows up in idleness and exhales itself in rhyme. While Oliver was thus piping and poetising at the parsonage, his uncle Contarine received a visit from Dean Goldsmith of Cloyne—a kind of magnate in the wide but improvident family connexion, throughout which his word was law and almost gospel. This august dignitary was pleased to discover signs of talent in Oliver, and suggested as he had attempted divinity and law without success, he should now try physic. The advice came from too important a source to be disregarded, and it was determined to send him to Edinburgh to commence his studies. The dean having given the advice, added to it, we trust, his blessing, but no money; that was furnished from the scantier purses of Goldsmith's brother, his sister (Mrs. Hodson), and his ever-ready uncle Contarine.

It was in the autumn of 1752 that Goldsmith arrived in Edinburgh. His outset in that city came near adding to the list of his indiscretions and disasters. Having taken lodgings at hap-hazard, he left his trunk there, containing all his worldly effects, and sallied forth to see the town. After sauntering about the streets until a late hour, he thought of returning home, when to his confusion, he found he had not acquainted himself with the name either of his landlady or of the street in which she lived. Fortunately, in the height of his whimsical perplexity, he met the cawdy or porter who had carried his trunk, and who now served him as a guide.

He did not remain long in the lodgings in which he had put up. The hostess was too adroit at that hocus pocus of the table which often is practised in cheap boarding-houses. No one could conjure a single joint through a greater variety of forms. A loin of mutton, according to Goldsmith's account, would serve him and two fellow-students a whole week. "A brandered chop was served up one day, a fried steak another, collops with onion sauce a third, and so on until the fleshy parts were quite consumed, when finally a dish of broth was manufactured from the bones on the seventh day, and the landlady rested from her labours." Goldsmith had a good-humoured mode of taking things, and for a short time amused himself with the shifts and expedients of his landlady, which struck him in a ludicrous manner; he soon, however, fell in with fellow-students from his own country, whom he joined at more eligible quarters.

He now attended medical lectures, and attached himself to an association of students called the Medical

Society. He set out, as usual, with the best intentions, but as usual soon fell into idle, convivial, thoughtless habits. Edinburgh was indeed a place of sore trial for one of his temperament. Convivial meetings were all the vogue, and the tavern was the universal rallying-place of good-fellowship. And then Goldsmith's intimacies lay chiefly among the Irish students, who were always ready for a wild freak and frolic. Among them he was a prime favourite and somewhat of a leader, from his exuberance of spirits, his vein of humour, and his talent at singing an Irish song and telling an Irish story.

His usual carelessness in money matters attended him. Though his supplies from home were scanty and irregular, he never could bring himself into habits of prudence and economy; often he lavished them away in fits of unguarded charity or generosity. Sometimes among his companions he assumed a ludicrous swagger in money matters, which no one afterwards was more ready than himself to laugh at. At a convivial meeting with a number of his fellow-students, he suddenly proposed to draw lots with any one present which of the two should treat the whole party to the play. The moment the proposition had bolted from his lips his heart was in his throat. "To my great though secret joy," said he, "they all declined the challenge. Had it been accepted, and had I proved the loser, a part of my wardrobe must have been pledged in order to raise the money."

At another of these meetings there was an earnest dispute on the question of ghosts, some being firm believers in the possibility of departed spirits returning to visit their friends and familiar haunts. One of the disputants set sail the next day for London, but the vessel put back through stress of weather. His return was unknown except to one of the believers in ghosts, who concerted with him a trick to be played off on the opposite party. In the evening, at a meeting of the students, the discussion was renewed; and one of the most strenuous opposers of ghosts was asked whether he considered himself proof against ocular demonstration? He persisted in his scoffing. Some solemn process of conjuration was performed, and the comrade supposed to be on his way to London made his appearance. The effect was fatal. The unbeliever fainted at the sight, and ultimately went mad. We have no account of what share Goldsmith took in this transaction, at which he was present.

The following letter to his friend Bryanton contains some of Goldsmith's impressions concerning Scotland and its inhabitants, and gives indications of that humour which characterised some of his late writings.

*"Robert Bryanton, at Ballymahon, Ireland."*

*"Edinburgh, Sept. 26th, 1753."*

"MY DEAR BOB,—How many good excuses (and you know I was ever good at an excuse) might I call up to vindicate my past shameful silence. I might tell how I wrote a long letter on my first coming hither, and seem vastly angry at my not receiving an answer; I might allege that business (with business you know I was always pestered) had never given me time to finger a pen. But I suppress those and twenty more as plausible, and as easily invented, since they might be attended with a slight inconvenience of being known to be lies. Let me then speak truth. An hereditary indolence (I have it from my mother's side) has hitherto prevented my writing to you, and still prevents my writing at least twenty-five letters more due to my friends in Ireland. No turnspit-dog gets up into his wheel with more reluctance than I sit down to write; yet no dog ever loved the roast meat he turns better than I do him I now address.

"Yet what shall I say now I am entered? Shall I tire you with a description of this unfruitful country, where I must lead you over their hills all brown with heath, or their valleys scarcely able to feed a rabbit?"

Man alone seems to be the only creature who has arrived to the natural size in this poor soil. Every part of the country presents the same dismal landscape. No grove nor brook lend their music to cheer the stranger, or make the inhabitants forget their poverty. Yet with all these disadvantages to call him down to humility, a Scotchman is one of the proudest things alive. The poor have pride ever ready to relieve them. If mankind should ever despise them, they are masters of their own admiration; and that they can plentifully bestow upon themselves.

"From their pride and poverty, as I take it, results one advantage this country enjoys; namely, the gentlemen here are much better bred than among us. No such character here as our fox-hunters; and they have expressed great surprise when I informed them that some men in Ireland of one thousand pounds a year spend their whole lives in running after a hare, and drinking to be drunk. Truly if such a being, equipped in his hunting dress, came among a circle of Scotch gentry, they would behold him with the same astonishment that a countryman does King George on horseback.

"The men here have generally high cheek-bones, and are lean and swarthy, fond of action, dancing in particular. Now that I have mentioned dancing, let me say something of their balls, which are very frequent here. When a stranger enters the dancing-hall, he sees one end of the room taken up by the ladies, who sit dismally in a group by themselves;—in the other end stand their pensive partners that are to be;—but no more intercourse between the sexes than there is between two countries at war. The ladies indeed may ogle, and the gentlemen sigh; but an embargo is laid on any closer commerce. At length, to interrupt hostilities, the lady-directress, or intendant, or what you will, pitches upon a lady and gentleman to walk a minuet, which they perform with a formality that approaches to despondence. After five or six couple have thus walked the gauntlet, all stand up to country-dances, each gentleman furnished with a partner from the aforesaid lady-directress; so they dance much, say nothing, and thus conclude our assembly. I told a Scotch gentleman that such profound silence resembled the ancient procession of the Roman matrons in honour of Ceres; and the Scotch gentleman told me (and, faith, I believe he was right) that I was a very great pedant for my pains.

"Now I am come to the ladies; and to show that I love Scotland, and everything that belongs to so charming a country, I insist on it, and will give him leave to break my head that denies it—that the Scotch ladies are ten thousand times finer and handsomer than the Irish. To be sure, now, I see your sisters, Betty and Peggy, vastly surprised at my partiality; tell them flattery I don't value them, or their fine skins, or eyes, or good sense, or—a potato;—for I say, and will maintain it, and as a convincing proof (I am in a great passion) of what I assert, the Scotch ladies say it themselves. But to be less serious; where will you find a language so prettily become a pretty mouth as the broad Scotch? And the women here speak it in its highest purity; for instance, teach one of your young ladies at home to pronounce the 'Whoar wull I gong?' with a becoming widening of the mouth, and I'll lay my life they'll wound every hearer.

"We have no such character here as a coquette, but alas! how many envious prudes? Some days ago I walked into my Lord Kilcoubry's (don't be surprised, my lord is but a glover),\* when the Duchess of Hamilton (that fair who sacrificed her beauty to her ambition, and her inward peace to a title and gilt equipage) passed by

in her chariot; her battered husband, or more properly speaking the guardian of her charms, sat by her side. Straight envy began, in the shape of no less than three ladies who sat with me, to find faults in her faultless form.—'For my part,' says the first, 'I think what I always thought, that the duchess has too much of the red in her complexion.' 'Madam, I am of your opinion,' says the second; 'I think her face has a palish cast, too much on the delicate order.' 'And, let me tell you,' added the third lady, whose mouth was puckered up to the size of an issue, 'that the duchess has fine lips, but she wants a mouth.'—At this every lady drew up her mouth as if going to pronounce the letter P.

"But how ill, my Bob, does it become me to ridicule women with whom I have scarcely any correspondence! There are, 'tis certain, handsome women here; and 'tis certain they have handsome men to keep them company. An ugly and poor man is society only for himself; and such society the world lets me enjoy in great abundance. Fortune has given you circumstances, and nature a person to look charming in the eyes of the fair. Nor do I envy my dear Bob such blessings, while I may sit down and laugh at the world and at myself—the most ridiculous object in it. But you see I am grown downright splenetic, and perhaps the fit may continue till I receive an answer to this. I know you cannot send me much news from Ballymahon, but such as it is, send it all; everything you send will be agreeable to me.

"Has George Conway put up a sign yet; or John Binley left off drinking drams; or Tom Allen got a new wig? But I leave you to your own choice what to write. While I live, know you have a true friend in yours, &c.

"OLIVER GOLDSMITH.

"P.S.—Give my sincere respects (not compliments, do you mind) to your agreeable family, and give my service to my mother, if you see her; for, as you express it in Ireland, I have a sneaking kindness for her still. Direct to me, —, Student in Physic, in Edinburgh."

Nothing worthy of preservation appeared from his pen during his residence in Edinburgh; and indeed his poetical powers, highly as they had been estimated by his friends, had not as yet produced anything of superior merit. He made on one occasion a month's excursion to the Highlands. "I set out the first day on foot," says he, in a letter to his uncle Contarine, "but an ill-natured corn I have on my toe has for the future prevented that cheap mode of travelling; so the second day I hired a horse about the size of a ram, and he walked away (trot he could not) as pensive as his master."

During his residence in Scotland his convivial talents gained him at one time attentions in a high quarter, which, however, he had the good sense to appreciate correctly. "I have spent," says he, in one of his letters, "more than a fortnight every second day at the Duke of Hamilton's; but it seems they like me more as a jester than as a companion, so I disdained so servile an employment as unworthy my calling as a physician." Here we again find the origin of another passage in his autobiography, under the character of the "Man in Black," wherein that worthy figures as a flatterer to a great man. "At first," says he, "I was surprised that the situation of a flatterer at a great man's table could be thought disagreeable; there was no great trouble in listening attentively when his lordship spoke, and laughing when he looked round for applause. This, even good manners might have obliged me to perform. I found, however, too soon, his lordship was a greater dunce than myself, and from that moment flattery was at an end. I now rather aimed at setting him right than at receiving his absurdities with submission. To flatter those we do not know is an easy task; but to flatter our intimate acquaintances, all whose foibles are strongly in our eyes, is drudgery insupportable. Every time I now opened my lips in praise, my falsehood went to my conscience; his lordship soon perceived me to be very unfit for his ser-

\* William Maclellan, who claimed the title, and whose son succeeded in establishing the claim in 1773. The father is said to have voted at the election of the sixteen Peers for Scotland; and to have sold gloves in the lobby of this and other public assemblies.

vice; I was therefore discharged—my patron at the same time being graciously pleased to observe that he believed I was tolerably good-natured, and had not the least harm in me."

After spending two winters at Edinburgh, Goldsmith prepared to finish his medical studies on the continent, for which his uncle Contarine agreed to furnish the funds. "I intend," said he, in a letter to his uncle, "to visit Paris, where the great Farheim, Petit, and Du Hammel de Monceau instruct their pupils in all the branches of medicine. They speak French, and consequently I shall have much the advantage of most of my countrymen, as I am perfectly acquainted with that language, and few who leave Ireland are so. I shall spend the spring and summer in Paris, and the beginning of next winter go to Leyden. The great Albinus is still alive there, and 'twill be proper to go, though only to have it said that we have studied in so famous a university."

"As I shall not have another opportunity of receiving money from your bounty till my return to Ireland, so I have drawn for the last sum that I hope I shall ever trouble you for; 'tis £20. And now, dear sir, let me acknowledge the humility of the station in which you found me; let me tell how I was despised by most, and hateful to myself. Poverty, hopeless poverty, was my lot, and Melancholy was beginning to make me her own. When you — but I stop here, to inquire how your health goes on? How does my cousin Jenny, and has she recovered her late complaint? How does my poor Jack Goldsmith? I fear his disorder is of such a nature as he won't easily recover. I wish, my dear sir, you would make me happy by another letter before I go abroad, for there I shall hardly hear from you. \* \* Give my—how shall I express it? Give my earnest love to Mr. and Mrs. Lawder."

Mrs. Lawder was Jane, his early playmate—the object of his valentine—his first poetical inspiration. She had been for some time married.

Medical instruction, it will be perceived, was the ostensible motive for this visit to the continent, but the real one, in all probability, was his long-cherished desire to see foreign parts. This, however, he would not acknowledge even to himself, but sought to reconcile his roving propensities with some grand moral purpose. "I esteem the traveller who instructs the heart," says he, in one of his subsequent writings, "but despise him who only indulges the imagination. A man who leaves home to mend himself and others is a philosopher; but he who goes from country to country, guided by the blind impulse of curiosity, is only a vagabond." He, of course, was to travel as a philosopher, and in truth his outfits for a continental tour were in character. "I shall carry just £33 to France," said he, "with a good store of clothes, shirts, &c., and that with economy will suffice." He forgot to make mention of his flute, which it will be found had occasionally to come in play when economy could not replenish his purse, nor philosophy find him a supper. Thus slenderly provided with money, prudence, or experience, and almost as slightly guarded against "hard knocks" as the hero of *La Mancha*, whose head-piece was half iron, half pasteboard, he made his final sally forth upon the world, hoping all things—believing all things; little anticipating the chequered ills in store for him—little thinking, when he penned his valedictory letter to his good uncle Contarine, that he was never to see him more—never to return after all his wandering to the friend of his infancy—never to revisit his early and fondly-remembered haunts at "sweet Lissoy" and Ballymahon.

## CHAP. V.

The agreeable fellow-passengers—Risks from friends picked up by the way-side—Sketches of Holland and the Dutch—Shifts while a poor student at Leyden—The tulip speculation—The provident flute—Sojourn at Paris—Sketch of Voltaire—Travelling shifts of a philosophic vagabond.

His usual indiscretion attended Goldsmith at the very outset of his foreign enterprise. He had intended to take shipping at Leith for Holland; but on arriving at that port he found a ship about to sail for Bordeaux, with six agreeable passengers, whose acquaintance he had probably made at the inn. He was not a man to resist a sudden impulse; so, instead of embarking for Holland, he found himself ploughing the seas on his way to the other side of the continent. Scarcely had the ship been two days at sea, when she was driven by stress of weather to Newcastle-upon-Tyne. Here, of course, Goldsmith and his agreeable fellow-passengers found it expedient to go on shore and "refresh themselves after the fatigues of the voyage." Of course they frolicked and made merry until a late hour in the evening, when, in the midst of their hilarity, the door was burst open, and a sergeant and twelve grenadiers entered with fixed bayonets, and took the whole convivial party prisoners.

It seems that the agreeable companions with whom our green-horn had struck up such a sudden intimacy were Scotchmen in the French service, who had been in Scotland enlisting recruits for the French army.

In vain Goldsmith protested his innocence: he was marched off with his fellow-revellers to prison, whence he with difficulty obtained his release at the end of a fortnight. With his customary facility, however, at palliating his misadventures, he found everything turn out for the best. His imprisonment saved his life, for during his detention the ship proceeded on her voyage, but was wrecked at the mouth of the Garonne, and all on board perished.

Goldsmith's second embarkation was for Holland direct, and in nine days he arrived at Rotterdam, whence he proceeded, without any more deviations, to Leyden. He gives a whimsical picture in one of his letters of the appearance of the Hollanders. "The modern Dutchman is quite a different creature from him of former times: he in everything imitates a Frenchman but in his easy, disengaged air. He is vastly ceremonious, and is, perhaps, exactly what a Frenchman might have been in the reign of Louis XIV. Such are the better bred. But the downright Hollander is one of the oddest figures in nature. Upon a lank head of hair he wears a half-cocked narrow hat, laced with black riband; no coat, but seven waistcoats and nine pair of breeches, so that his hips reach up almost to his armpits. This well-clothed vegetable is now fit to see company or make love. But what a pleasing creature is the object of his appetite! why, she wears a large fur cap, with a deal of Flanders lace; and for every pair of breeches he carries she puts on two petticoats.

"A Dutch lady burns nothing about her phlegmatic admirer but his tobacco. You must know, sir, every woman carries in her hand a stove of coals, which, when she sits, she snugs under her petticoats, and at this chimney dozing Strephon lights his pipe."

In the same letter he contrasts Scotland and Holland. "There, hills and rocks intercept every prospect; here, it is all a continued plain. There you might see a well-dressed duchess issuing from a dirty close, and here a dirty Dutchman inhabiting a palace. The Scotch may be compared to a tulip planted in dung; but I can never see a Dutchman in his own house but I think of a magnificent Egyptian temple dedicated to an ox.

The country itself awakened his admiration. "Nothing," said he, "can equal its beauty; wherever I turn my eyes, fine houses, elegant gardens, statues, grottoes,

vistas, present themselves; but when you enter their towns you are charmed beyond description. No misery is to be seen here; every one is usefully employed." And again, in his noble description in "The Traveller:"

To men of other minds my fancy flies,  
Embosom'd in the deep where Holland lies.  
Methinks her patient sons before me stand,  
Where the broad ocean leans against the land,  
And, sedulous to stop the coming tide,  
Lift the tall rampire's artificial pride.  
Onward, methinks, and diligently slow,  
The firm connected bulwark seems to grow;  
Spreads its long arms amid the watery roar,  
Scoops out an empire, and usurps the shore.  
While the pent ocean, rising o'er the pile,  
Sees an amphibious world before him smile;  
The slow canal, the yellow-blossom'd vale,  
The willow-tufted bank, the gliding sail,  
The crowded mart, the cultivated plain,  
A new creation rescued from his reign.

He remained about a year at Leyden, attending the lectures of Gaubius on chemistry, and Albinus on anatomy; though his studies are said to have been miscellaneous, and directed to literature rather than science. The thirty-three pounds with which he had set out on his travels were soon consumed, and he was put to many a shift to meet his expenses until his precarious remittances should arrive. He had a good friend on these occasions in a fellow-student and countryman, named Ellis, who afterwards rose to eminence as a physician. He used frequently to loan small sums to Goldsmith, which were always scrupulously paid. Ellis discovered the innate merits of the poor awkward student, and used to declare in after life that it was a common remark in Leyden, that in all the peculiarities of Goldsmith an elevation of mind was to be noted—a philosophical tone and manner—the feelings of a gentleman, and the language and information of a scholar.

Sometimes in his emergencies Goldsmith undertook to teach the English language. It is true he was ignorant of the Dutch, but he had a smattering of the French, picked up among the Irish priests at Ballymahon. He depicts his whimsical embarrassment in this respect in his account in the "Vicar of Wakefield" of the *philosophical vagabond*, who went to Holland to teach the natives English without knowing a word of their own language. Sometimes, when sorely pinched, and sometimes, perhaps, when flush, he resorted to the gambling tables, which in those days abounded in Holland. His good friend Ellis repeatedly warned him against this unfortunate propensity, but in vain. It brought its own cure, or rather its own punishment, by stripping him of every shilling.

Ellis once more stepped in to his relief with a true Irishman's generosity, but with more considerateness than generally characterises an Irishman, for he only granted pecuniary aid on condition of his quitting the sphere of danger. Goldsmith gladly consented to leave Holland, being anxious to visit other parts. He intended to proceed to Paris and pursue his studies there, for which purpose he was furnished by his friend with money for the journey. Unluckily, he rambled into the garden of a florist just before quitting Leyden. The tulip mania was still prevalent in Holland, and some species of that splendid flower brought immense prices. In wandering through the garden, Goldsmith recollected that his uncle Contarine was a tulip-fancier. The thought suddenly struck him that here was an opportunity of testifying in a delicate manner his sense of that generous uncle's past kindnesses. In an instant his hand was in his pocket; a number of choice and costly tulip-roots were purchased and packed up for Mr. Contarine; and it was not until he had paid for them that he bethought himself that he had spent all the money borrowed for his travelling expenses. Too proud, however, to give up his journey, and too shamefaced to make another appeal to his friend's liberality, he determined to travel on foot, and depend

upon chance and good luck for the means of getting forward; and it is said that he actually set off on a tour of the continent in February, 1775, with but one spare shirt, a flute, and a single guinea.

"Blessed," says one of his biographers, "with a good constitution, an adventurous spirit, and with that thoughtless, or, perhaps, happy disposition which takes no care for to-morrow, he continued his travels for a long time in spite of innumerable privations." In his amusing narrative of the adventures of a "Philosophic Vagabond" in the "Vicar of Wakefield," we find shadowed out the expedients he pursued. "I had some knowledge of music, with a tolerable voice; I now turned what was once my amusement into a present means of subsistence. I passed among the harmless peasants of Flanders, and among such of the French as were poor enough to be very merry, for I ever found them sprightly in proportion to their wants. Whenever I approached a peasant's house towards nightfall I played one of my merriest tunes, and that procured me not only lodging, but subsistence for the next day; but in truth I must own, whenever I attempted to entertain persons of a higher rank they always thought my performances odious, and never made me any return for my endeavours to please them."

At Paris he attended the chemical lectures of Rouelle, then in great vogue, where he says he witnessed as bright a circle of beauty as graced the court of Versailles. His love of theatricals, also, led him to attend the performances of the celebrated actress Mademoiselle Clairon, with which he was greatly delighted. He seems to have looked upon the state of society with the eye of a philosopher, but to have read the signs of the times with the prophetic eye of a poet. In his rambles about the environs of Paris, he was struck with the immense quantities of game running about almost in a tame state; and saw in those costly and rigid preserves for the amusement and luxury of the privileged few a sure "badge of the slavery of the people." This slavery he predicted was drawing towards a close. "When I consider that these parliaments, the members of which are all created by the court, and the presidents of which can only act by immediate direction, presume even to mention privileges and freedom, who till of late received directions from the throne with implicit humility; when this is considered, I cannot help fancying that the genius of Freedom has entered that kingdom in disguise. If they have but three weak monarchs more successively on the throne the mask will be laid aside, and the country will certainly once more be free." Events have testified to the sage forecast of the poet.

During a brief sojourn in Paris he appears to have gained access to valuable society, and to have had the honour and pleasure of making the acquaintance of Voltaire; of whom, in after years, he wrote a memoir. "As a companion," says he, "no man ever exceeded him when he pleased to lead the conversation—which, however, was not always the case. In company which he either disliked or despised, few could be more reserved than he; but when he was warmed in discourse, and got over a hesitating manner which sometimes he was subject to, it was rapture to hear him. His meagre visage seemed insensibly to gather beauty; every muscle in it had meaning, and his eye beamed with unusual brightness. The person who writes this memoir," continues he "remembers to have seen him in a select company of wits of both sexes in Paris, when the subject happened to turn upon English taste and learning. Fontenelle (then nearly a hundred years old), who was one of the party, and who being unacquainted with the language or authors of the country he undertook to condemn, with a spirit truly vulgar, began to revile both. Diderot, who liked the English, and knew something of their literary pretensions, attempted to vindicate their poetry and learning, but with unequal abilities.

The company quickly perceived that Fontenelle was superior in the dispute, and were surprised at the silence which Voltaire had preserved all the former part of the night, particularly as the conversation happened to turn upon one of his favourite topics. Fontenelle continued his triumph until about twelve o'clock, when Voltaire appeared at last roused from his reverie. His whole frame seemed animated. He began his defence with the utmost defiance mixed with spirit, and now and then let fall the finest strokes of raillery upon his antagonist; and his harangue lasted till three in the morning. I must confess that, whether from natural partiality or from the elegant sensibility of his manner, I never was so charmed, nor did I ever remember so absolute a victory as he gained in this dispute." Goldsmith's ramblings took him into Germany and Switzerland, from which last-mentioned country he sent to his brother in Ireland the first brief sketch, afterwards amplified into his poem of the "Traveller."

At Geneva he became travelling tutor to a mongrel young gentleman, son of a London pawnbroker, who had been suddenly elevated into fortune and absurdity by the death of an uncle. The youth, before setting up for a gentleman, had been an attorney's apprentice, and was an arrant pettifogger in money matters. Never were two beings more oppositely assorted than he and Goldsmith. We may form an idea of the tutor and the pupil from the following extract from the narrative of the "Philosophic Vagabond."

"I was to be the young gentleman's governor, but with a proviso that he should always be permitted to govern himself. My pupil, in fact, understood the art of guiding in money concerns much better than I. He was heir to a fortune of about two hundred thousand pounds, left him by an uncle in the West Indies; and his guardians, to qualify him for the management of it, had bound him an apprentice to an attorney. Thus avarice was his prevailing passion; all his questions on the road were, how money might be saved—which was the least expensive course of travel—whether anything could be bought that would turn to account when disposed of again in London? Such curiosities on the way as could be seen for nothing he was ready enough to look at; but if the sight of them was to be paid for, he usually asserted that he had been told that they were not worth seeing. He never paid a bill that he would not observe how amazingly expensive travelling was; and all this though not yet twenty-one."

In this sketch, Goldsmith undoubtedly shadows forth his annoyances as travelling tutor to this concrete young gentleman, compounded of the pawnbroker, the pettifogger, and the West Indian heir, with an overlaying of the city miser. They had continual difficulties on all points of expense until they reached Marseilles, where both were glad to separate.

Once more on foot, but freed from the irksome duties of "bear-leader," and with some of his pay, as tutor, in his pocket, Goldsmith continued his half-vagrant peregrinations through part of France and Piedmont, and some of the Italian States. He had acquired, as has been shown, a habit of shifting along and living by expedients, and a new one presented itself in Italy. "My skill in music," says he, in the "Philosophic Vagabond," could avail me nothing in a country where every peasant was a better musician than I; but by this time I had acquired another talent, which answered my purpose as well, and this was a skill in disputation. In all the foreign universities and convents there are, upon certain days, philosophical theses maintained against every adventurous disputant: for which, if the champion opposes with zeal and dexterity, he can claim a gratuity in money, a dinner, and a bed for one night." Though a poor wandering scholar, his reception in these learned piles was as free from humiliation as in the cottages of the peasantry. "With the members of these establish-

ments," said he, "I could converse on topics of literature, and then I always forgot the meanness of the circumstances."

At Padua, where he remained some months, he is said to have taken his medical degree. It is probable he was brought to a pause in this city by the death of his uncle Contarine; who had hitherto assisted him in his wanderings by occasional, though, of course, slender remittances. Deprived of this source of supplies, he wrote to his friends in Ireland, and especially to his brother-in-law, Hodson, describing his destitute situation. His letters brought him neither money nor reply. It appears, from subsequent correspondence, that his brother-in-law actually exerted himself to raise a subscription for his assistance among his relatives, friends, and acquaintance, but without success. Their faith and hope in him were most probably at an end; as yet he had disappointed them at every point—he had given none of the anticipated proofs of talent, and they were too poor to support what they may have considered the wandering propensities of a heedless spendthrift.

Thus left to his own precarious resources, Goldsmith gave up all further wandering in Italy, without visiting the south, though Rome and Naples must have held out powerful attractions to one of his poetical cast. Once more resuming his pilgrim staff, he turned his face toward England, "walking along from city to city, examining mankind more nearly, and seeing both sides of the picture." In traversing France, his flute—his magic flute!—was once more in requisition, as we may conclude by the following passage in his Traveller:—

Gay, sprightly land of mirth and social ease,  
Pleased with thyself, whom all the world can please.  
How often have I led thy sportive choir  
With tuneless pipe beside the murmuring Loire!  
Where shading elms along the margin grew,  
And freshened from the wave the zephyr flew;  
And haply, though my harsh note falt'ring still,  
But mocked all tune, and marr'd the dancer's skill;  
Yet would the village praise my wondrous power,  
And dance forgetful of the noontide hour.  
Alike all ages. Dames of ancient days  
Have led their children through the mirthful maze,  
And the gay grandsire, skilful in gestic lore,  
Has triak'd beneath the burden of three-score.

## CHAP. VI.

Landing in England—Shifts of a man without money—The pestle and mortar—Theatricals in a barn—Launch upon London—A city night scene—Struggles with penury—Miseries of a tutor—A doctor in the suburb—Poor practice and second-hand finery—A tragedy in embryo—Project of the written mountains.

After two years spent in roving about the continent, "pursuing novelty," as he said, "and losing content," Goldsmith landed at Dover early in 1756. He appears to have had no definite plan of action. The death of his uncle Contarine, and the neglect of his relatives and friends to reply to his letters, seem to have produced in him a temporary feeling of loneliness and destitution, and his only thought was to get to London, and throw himself upon the world. But how was he to get there? His purse was empty. England was to him as completely a foreign land as any part of the continent; and where on earth is a penniless stranger more destitute? His flute and his philosophy were no longer of any avail; the English bores cared nothing for music; there were no convents; and as to the learned and the clergy, not one of them would give a vagrant scholar a supper and a night's lodging for the best theses that ever was argued. "You may easily imagine," says he, in a subsequent letter to his brother-in-law, "what difficulties I had to encounter, left as I was without friends, recommendations, money, or impudence, and

that in a country, where being born an Irishman was sufficient to keep me unemployed. Many in such circumstances would have had recourse to the friar's cord or the suicide's halter. But with all my follies, I had principle to resist the one and resolution to combat the other."

He applied at one place, we are told, for employment in the shop of a country apothecary; but all his medical science gathered in foreign universities could not gain him the management of a pestle and mortar. He even resorted, it is said, to the stage as a temporary expedient, and figured in low comedy at a country town in Kent. This accords with his last shift of the *Philosophic Vagabond*, and with the knowledge of country theatricals displayed in his "*Adventures of a Strolling Player*," or perhaps a story suggested by them. All this part of his career, however, in which he must have trod the lowest paths of humility, are only to be conjectured from vague traditions, or scraps of autobiography gleaned from his miscellaneous writings.

At length we find him launched on the great metropolis, or rather drifting about its streets at night, in the gloomy month of February, with but a few halfpence in his pocket. The deserts of Arabia are not more dreary and inhospitable than the streets of London at such a time, and to a stranger in such a plight. Do we want a picture as an illustration? We have it in his own works, and furnished, doubtless, from his own experience.

"The clock has just struck two; what a gloom hangs all around! no sound is heard but of the chiming clock, or the distant watch-dog. How few appear in those streets, which but some few hours ago were crowded! But who are those who make the streets their couch, and find a short repose from wretchedness at the doors of the opulent? They are strangers, wanderers, and orphans, whose circumstances are too humble to expect redress, and whose distresses are too great even for pity. Some are without the covering even of rags, and others emaciated with disease; the world has disclaimed them; society turns its back upon their distress, and has given them up to nakedness and hunger. These poor shivering females have once seen happier days, and been flattered into beauty. They are now turned out to meet the severity of winter. Perhaps, now, lying at the doors of their betrayers, they sue to wretches whose hearts are insensible, or debauchees who may curse but will not relieve them.

"Why, why was I born a man, and yet see the sufferings of wretches I cannot relieve! Poor houseless creatures! The world will give you reproaches, but will not give you relief."

Poor houseless Goldsmith! we may here ejaculate—to what shifts he must have been driven to find shelter and sustenance for himself in this first adventure into London! Many years afterwards, in the days of his social elevation, he started a polite circle at Sir Joshua Reynolds's by humorously relating an anecdote about the time he "lived among the beggars of Axe Lane." Such may have been the desolate quarters with which he was fain to content himself when thus adrift upon the town, with but a few halfpence in his pocket.

The first authentic trace we have of him in this new part of his career, is filling the situation of an usher to a school; and even this employ he obtained with some difficulty, after a reference for a character to his friends in the University of Dublin. In the "*Vicar of Wakefield*" he makes George Primrose undergo a whimsical catechism concerning the requisites for an usher. "Have you been apprentice to the business?" "No." "Then you won't do for a school. Can you dress the boys' hair?" "No." "Then you won't do for a school. Can you lie three in a bed?" "No." "Then you will never do for a school. Have you a good stomach?" "Yes." "Then you will by no means do for a school." I have

been an usher in a boarding-school myself, and may I die of an anodyne necklace, but I had rather be under-turkey in Newgate. I was up early and late: I was browbeat by the master, hated for my ugly face by the mistress, and worried by the boys."

Goldsmith remained but a short time in this situation, and to the mortifications experienced there we doubtless owe the picturings given in his writings of the hardships of an usher's life.

"He is generally," says he "the laughing-stock of the school. Every trick is played upon him; the oddity of his manner, his dress or his language, is a fund of eternal ridicule; the master himself now and then cannot avoid joining in the laugh; and the poor wretch, eternally resenting this ill usage, lives in a state of war with all the family." . . . "He is obliged, perhaps, to sleep in the same bed with the French teacher, who disturbs him for an hour every night in preparing and filleting his hair, and stinks worse than carrion with his rancid pomatums when he lays his head beside him on the bolster."

His next shift was as assistant in the laboratory of a chemist near Fish street Hill. After remaining here a few months, he heard that Dr. Sleight, who had been his friend and fellow-student at Edinburgh, was in London. Eager to meet with a friendly face in this land of strangers, he immediately called on him; "but though it was Sunday, and it is to be supposed I was in my best clothes, Sleight scarcely knew me—such is the tax the unfortunate pay to poverty. However, when he did recollect me, I found his heart as warm as ever, and he shared his purse and friendship with me during his continuance in London."

Through the advice and assistance of Dr. Sleight, he now commenced the practice of medicine, but in a small way, in Bankside, Southwark, and chiefly among the poor; for he wanted the figure, address, polish, and management to succeed among the rich. His old school-mate and college companion, Beatty, who used to aid him with his purse at the university, met him about this time, decked out in the tarnished finery of a second-hand suit of green and gold, with a shirt and neckcloth of a fortnight's wear.

Poor Goldsmith endeavoured to assume a prosperous air in the eyes of his early associate. "He was practising physic" he said, "and doing very well!" At this moment poverty was pinching him to the bone in spite of his practice and his dirty finery. His fees were necessarily small and ill paid, and he was fain to seek some precarious assistance from his pen. Here his quondam fellow-student, Dr. Sleight, was again of service, introducing him to some of the booksellers, who gave him occasional, though starving employment. According to tradition, however, his most efficient patron just now was a journeyman printer, one of his poor patients of Bankside; who had formed a good opinion of his talents, and perceived his poverty and his literary shifts. The printer was in the employ of Mr. Samuel Richardson, the author of *Pamela*, *Clarissa*, and *Sir Charles Grandison*, who combined the novelist and the publisher, and was in flourishing circumstances. Through the journeyman's intervention Goldsmith is said to have become acquainted with Richardson, who employed him as reader and corrector of the press, at his printing establishment in Salisbury court; an occupation which he alternated with his medical duties.

Being admitted occasionally to Richardson's parlour, he began to form literary acquaintances, among whom the most important was Dr. Young, the author of "*Night Thoughts*," a poem in the height of fashion. It is not probable, however, that much familiarity took place at the time between the literary lion of the day and the poor *Æsculapius* of Bankside, the humble corrector of the press. Still the communion with literary men had its effect to set his imagination teeming. Dr.

Farr, one of his Edinburgh fellow students, who was at London about this time attending the hospital and lectures, gives us an amusing account of Goldsmith in his literary character.

"Early in January he called upon me one morning before I was up, and, on my entering the room, I recognised my old acquaintance, dressed in a rusty, full-trimmed black suit, with his pocket full of papers, which instantly reminded me of the poet in Garrick's farce of *Lethæ*. After we had finished our breakfast, he drew from his pocket part of a tragedy, which he said he had brought for my correction. In vain I pleaded inability, when he began to read; and every part on which I expressed a doubt as to the propriety was immediately blotted out. I then most earnestly pressed him not to trust to my judgment, but to take the opinion of persons better qualified to decide on dramatic compositions. He now told me he had submitted his production, so far as he had written, to Mr. Richardson, the author of *Clarissa*, on which I peremptorily declined offering another criticism on the performance."

From the graphic description given of him by Dr. Farr, it will be perceived that the tarnished finery of green and gold had been succeeded by a professional suit of black, to which, we are told, were added the wig and cane indispensable to medical doctors in those days. The coat was a second-hand one, of rusty velvet, with a patch on the left breast, which he adroitly covered with his three-cornered hat during his medical visits; and we have an amusing anecdote of his contest of courtesy with a patient who persisted in endeavouring to relieve him from the hat, which only made him press it more devoutly to his heart.

Nothing further has ever been heard of the tragedy mentioned by Dr. Farr; it was probably never completed. The same gentleman speaks of a strange Quixotic scheme which Goldsmith had in contemplation at the time, "of going to decipher the inscriptions on the written mountains," though he was altogether ignorant of Arabic, or the language in which they might be supposed to be written. "The salary of three hundred pounds," adds Dr. Farr, "which had been left for the purpose, was the temptation." This was probably one of many dreamy projects with which his fervid brain was apt to teem. On such subjects he was prone to talk vaguely and magnificently, but inconsiderately, from a kindled imagination rather than a well-instructed judgment. He had always a great notion of expeditions to the East, and wonders to be seen and effected in the Oriental countries.

## CHAP. VII.

*Life of a pedagogue—Kindness to schoolboys—Pertness in return—Expensive charities—The Griffiths and the "Monthly Review"—Toils of a literary hack—Rupture with the Griffiths.*

Among the most cordial of Goldsmith's intimates in London during this time of precarious struggle were certain of his former fellow-students in Edinburgh. One of these was the son of a Dr. Milner, a dissenting minister, who kept a classical school of eminence at Peckham, in Surrey. Young Milner had a favourable opinion of Goldsmith's abilities and attainments, and cherished for him that good with which his genial nature seems ever to have inspired among his school and college associates. His father falling ill, the young man negotiated with Goldsmith to take temporary charge of the school. The latter readily consented, for he was discouraged by the slow growth of medical reputation and practice, and as yet had no confidence in the coy smiles of the muse. Laying by his wig and cane, therefore, and once more wielding the ferule, he resumed the character of the pedagogue, and for some time reigned as

vicegerent over the academy at Peckham. He appears to have been well treated by both Dr. Milner and his wife; and became a favourite with the scholars from his easy, indulgent good nature. He mingled in their sports; told them droll stories; played on the flute for their amusement, and spent his money in treating them to sweetmeats and other schoolboy dainties. His familiarities were sometimes carried too far; he indulged in boyish pranks and practical jokes, and drew upon himself retorts in kind, which, however, he bore with great good humour. Once, indeed, he was touched to the quick by a piece of schoolboy pertness. After playing on the flute, he spoke with enthusiasm of music, as delightful in itself, and as a valuable accomplishment for a gentleman, whereupon a youngster, with a glance at his ungainly person, wished to know if he considered himself a gentleman. Poor Goldsmith, feelingly alive to the awkwardness of his appearance and the humility of his situation, winced at this unthinking sneer, which long rankled in his mind.

As usual, while in Dr. Milner's employ, his benevolent feelings were a heavy tax upon his purse, for he never could resist a tale of distress, and was apt to be fleeced by every sturdy beggar; so that between his charity and his munificence he was generally in advance of his slender salary. "You had better, Mr Goldsmith, let me take care of your money," said Mrs. Milner, one day, "as I do for some of the young gentlemen."—"In truth, madam, there is equal need!" was the good-humoured reply.

Dr. Milner was a man of some literary pretensions, and wrote occasionally for the "*Monthly Review*," of which a bookseller, by the name of Griffiths, was proprietor. This work was an advocate for Whig principles, and had been in prosperous existence for nearly eight years. Of late, however, periodicals had multiplied exceedingly, and a formidable Tory rival had started up in the "*Critical Review*," published by Archibald Hamilton, a bookseller, and aided by the powerful and popular pen of Dr. Smollett. Griffiths was obliged to recruit his forces. While so doing, he met Goldsmith, an humble occupant of a seat at Dr. Milner's table, and was struck with remarks on men and books which fell from him in the course of conversation. He took occasion to sound him privately as to his inclination and capacity as a reviewer, and was furnished by him with specimens of his literary and critical talents. They proved satisfactory. The consequence was that Goldsmith once more changed his mode of life, and in April, 1757, became a contributor to the "*Monthly Review*," at a small fixed salary, with board and lodging; and accordingly took up his abode with Mr. Griffiths, at the sign of the Dunciad, Paternoster-row. As usual, we trace this phase of his fortunes in his semipictitious writings; his sudden transmutation of the pedagogue into the author being humorously set forth in the case of "*George Primrose*," in the "*Vicar of Wakefield*." "Come," says George's adviser, "I see you are a lad of spirit and some learning; what do you think of commencing author, like me? You have read in books, no doubt, of men of genius starving at the trade: at present I'll show you forty very dull fellows about town that live by it in opulence—all honest, jog-trot men, who go on smoothly and dully, and write history and politics, and are praised; men, sir, who had they been bred cobblers would all their lives only have mended shoes, but never made them." "Finding," says George, "that there was no great degree of gentility affixed to the character of an usher, I resolved to accept his proposal; and, having the highest respect for literature, hailed the *antiqua mater* of Grub-street with reverence. I thought it my glory to pursue a track which Dryden and Otway trod before me." Alas! Dryden struggled with indigence all his days; and Otway, it is said, fell a victim to famine in his thirty-fifth year, being strangled by a roll of bread,

which he devoured with the voracity of a starving man.

In Goldsmith's experience the track soon proved a thorny one; Griffiths was a hard business man, of shrewd, worldly good sense, but little refinement or cultivation. He meddled, or rather muddled, with literature, too, in a business way, altering and modifying occasionally the writings of his contributors; and in this he was aided by his wife, who, according to Smollett, was an antiquated female critic and a dabbler in the "Review." Such was the literary vassalage to which Goldsmith had unwarily subjected himself. A diurnal drudgery was imposed on him, irksome to his indolent habits, and attended by circumstances humiliating to his pride. He had to write daily from nine o'clock until two, and often throughout the day, whether in the vein or not, and on subjects dictated by his task-master, however foreign to his taste; in a word, he was treated as a mere literary hack. But this was not the worst; it was the critical supervision of Griffiths and his wife which grieved him: the "illiterate bookselling Griffiths," as Smollett called them, "who presumed to revise, alter, and amend the articles contributed to their 'Review.' Thank heaven," crowed Smollett, "the 'Critical Review' is not written under the restraint of a bookseller and his wife. Its principal writers are independent of each other, unconnected with booksellers and unawed by old women!"

This literary vassalage, however, did not last long. The bookseller became more and more exacting. He accused his hack writer of idleness—of abandoning his writing-desk and literary workshop at an early hour of the day, and of assuming a tone and manner *above his situation*. Goldsmith, in return, charged him with impertinence, his wife with meanness and parsimony in her household treatment of him, and both of literary meddling and marring. The engagement was broken off at the end of five months by mutual consent, and without any violent rupture, as it will be found they afterwards had occasional dealings with each other.

Though Goldsmith was now nearly thirty years of age, he had produced nothing to give him a decided reputation. He was as yet a mere writer for bread. The articles he had contributed to the "Review" were anonymous, and were never avowed by him. They have since been, for the most part, ascertained; and though thrown off hastily, often treating on subjects of temporary interest, and marred by the Griffith interpolations, they are still characterised by his sound, easy good sense, and the genial graces of his style. Johnson observed that Goldsmith's genius flowered late; he should have said it flowered early, but was late in bringing its fruit to maturity.

#### CHAP. VIII.

Newbery, of picture-book memory—How to keep up appearances—Miseries of authorship—A poor relation—Letter to Hodson.

Being now known in the publishing world, Goldsmith began to find casual employment in various quarters; among others he wrote occasionally for the "Literary Magazine," a production set on foot by Mr. John Newbery, bookseller, St. Paul's Churchyard, renowned in nursery literature throughout the latter half of the last century for his picture-books for children. Newbery was a worthy, intelligent, kind-hearted man, and a seasonable, though cautious friend to authors, relieving them with small loans when in pecuniary difficulties, though always taking care to be well repaid by the labour of their pens. Goldsmith introduces him in a humorous yet friendly manner in his novel of the "Vicar of Wakefield." "This person was no other than the philanthropic bookseller in St. Paul's Churchyard, who has written so many little books for children; he called himself their friend; but he was the friend of all mankind. He was no sooner

alighted but he was in haste to be gone; for he was ever on business of importance, and was at that time actually compiling materials for the history of one Mr. Thomas Trip. I immediately recollected this good-natured man's red-pimpled face."

Besides his literary job-work, Goldsmith also resumed his medical practice, but with very trifling success. The scantiness of his purse still obliged him to live in obscure lodgings somewhere in the vicinity of Salisbury-square, Fleet-street; but his extended acquaintance and rising importance caused him to consult appearances. He adopted an expedient, then very common, and still practised in London among those who have to tread the narrow path between pride and poverty; while he burrowed in lodgings suited to his means, he "hailed," as it is termed, from the Temple Exchange Coffee-house near Temple Bar. Here he received his medical calls; hence he dated his letters, and here he passed much of his leisure hours, conversing with the frequenters of the place. "Thirty pounds a year," said a poor Irish painter, who understood the art of shifting, "is enough to enable a man to live in London without being contemptible. Ten pounds will find him in clothes and linen; he can live in a garret on eighteen-pence a week; hail from a coffee-house, where, by occasionally spending threepence, he may pass some hours each day in good company; he may breakfast on bread and milk for a penny; dine for sixpence; do without supper; and on *clean-shirt day* he may go abroad and pay visits."

Goldsmith seems to have taken a leaf from this poor devil's manual, in respect to the coffee-house at least. Indeed, coffee-houses in those days were the resorts of wits and literati, where the topics of the day were gossiped over, and the affairs of literature and the drama discussed and criticised. In this way he enlarged the circle of his intimacy, which now embraced several names of notoriety.

Do we want a picture of Goldsmith's experience in this part of his career, we have it in his observations on the life of an author in the "Inquiry into the State of Polite Learning," published some years afterwards.

"The author unpatronised by the great has naturally recourse to the bookseller. There cannot, perhaps, be a combination more prejudicial to taste than this. It is the interest of the one to allow as little for writing, and for the other to write as much as possible; accordingly tedious compilations and periodical magazines are the result of their joint endeavours. In these circumstances the author bids adieu to fame; he writes for bread; and for that only imagination is seldom called in. He sits down to address the venal muse with the most phlegmatic apathy; and, as we are told of the Russian, courts his mistress by falling asleep in her lap."

Again. "Those who are unacquainted with the world are apt to fancy the man of wit as leading a very agreeable life. They conclude, perhaps, that he is attended with silent admiration, and dictates to the rest of mankind with all the eloquence of conscious superiority. Very different is his present situation. He is called an author, and all know that an author is a thing only to be laughed at. His person, not his jest, becomes the mirth of the company. At his approach the most fat, unthinking face brightens into malicious meaning. Even aldermen laugh, and avenge on him the ridicule which was lavished on their forefathers." \* \* \* "The poet's poverty is a standing topic of contempt. His writing for bread is an unpardonable offence. Perhaps, of all mankind, an author in these times is used most hardly. We keep him poor, and yet revile his poverty. We reproach him for living by his wit, and yet allow him no other means to live. His taking refuge in garrets and cellars has of late been violently objected to him, and that by men who, I have hope, are more apt to pity than insult his distress. Is poverty a careless fault? No doubt he knows how to prefer a bottle of champagne to the nectar of the neighbouring alehouse, or a venison

pasty to a plate of potatoes. Want of delicacy is not in him, but in those who deny him the opportunity of making an elegant choice. Wit certainly is the property of those who have it; nor should we be displeased if it is the only property a man sometimes has. We must not underrate him who uses it for subsistence, and flees from the ingratitude of the age, even to a bookseller, for redress." \* \* \* \* \*

"If the author be necessary among us, let us treat him with proper consideration as a child of the public, not as a rent-charge on the community. And indeed a child of the public he is in all respects; for while so well able to direct others, how frequently is he found incapable of guiding himself. His simplicity exposes him to all the insidious approaches of cunning—his sensibility to the slightest invasions of contempt. Though possessed of fortitude to stand unmoved the expected bursts of an earthquake, yet of feelings so exquisitely poignant as to agonize under the slightest disappointment. Broken rest, tasteless meals, and causeless anxieties shorten life, and render it unfit for active enjoyments; prolonged vigils and intense application still farther contract his span, and make his time glide insensibly away."

While poor Goldsmith was thus struggling with the difficulties and discouragements which in those days beset the path of an author, his friends in Ireland received accounts of his literary success, of the distinguished acquaintances he was making. This was enough to put the wise heads at Lissoy and Ballymahon in a ferment of conjectures. With the exaggerated notions of provincial relatives concerning the family great man in the metropolis, some of Goldsmith's poor kindred pictured him to themselves seated in high places, clothed in purple and fine linen, and hand and glove with the givers of gifts and dispensers of patronage. Accordingly, he was one day surprised at the sudden apparition, in his miserable lodging, of his younger brother Charles, a raw youth of twenty-one, endowed with a double share of the family heedlessness, and who expected to be forthwith helped into some snug by-path to fortune by one or other of Oliver's great friends. Charles was sadly disconcerted on learning that, so far from being able to provide for others, his brother could scarcely take care of himself. He looked round with a rueful eye on the poet's quarters, and could not help expressing his surprise and disappointment at finding him no better off. "All in good time, my dear boy," replied poor Goldsmith, with infinite good humour; "I shall be richer by-and-by. Addison, let me tell you, wrote his poem of the 'Campaign' in a garret in the Haymarket, three stories higher and you see I am not come to that yet, for I have only got to the second story."

Charles Goldsmith did not remain long to embarrass his brother in London. With the same roving disposition and inconsiderate temper of Oliver, he suddenly departed in an humble capacity to seek his fortune in the West Indies, and nothing was heard of him for above thirty years, when, after having been given up as dead by friends, he made his reappearance in England.

Shortly after his departure, Goldsmith wrote a letter to his brother-in-law, Daniel Hodson, Esq., of which the following is an extract; it was partly intended, no doubt, to dissipate any further illusions concerning his fortunes which might float on the magnificent imagination of his friends in Ballymahon.

"I suppose you desire to know my present situation. As there is nothing in it at which I should blush or which mankind could censure, I see no reason for making it a secret. In short, by a very little practice as a physician, and a very little reputation as a poet, I make a shift to live. Nothing is more apt to introduce us to the gates of the muses than poverty; but it were well if they only left us at the door. The mischief is, they sometimes choose to give us their company to the

entertainment; and Want, instead of being gentleman usher, often turns master of the ceremonies.

"Thus, upon learning I write, no doubt you imagine I starve; and the name of an author naturally reminds you of a garret. In this particular I do not think proper to undeceive my friends. But, whether I eat or starve, live in a first floor or four pair of stairs high, I still remember them with ardour; nay, my very country comes in for a share of my affection. Unaccountable fondness for country, this *maladie du pays*, as the French call it! Unaccountable that he should still have an affection for a place, who never, when in it, received above common civility; who never brought anything out of it except his brogue and his blunders. Surely my affection is equally ridiculous with the Scotchman's, who refused to be cured of the itch, because it made him unco' thoughtful of his wife and bonny Inverary.

"But now, to be serious: let me ask myself what gives me a wish to see Ireland again? The country is a fine one, perhaps? No. There is good company in Ireland? No. The conversation there is generally made up of a smutty toast or a bawdy song; the vivacity supported by some humble cousin, who had just folly enough to earn his dinner. Then, perhaps, there's more wit and learning among the Irish? Oh, Lord, no! There has been more money spent in the encouragement of the Padareen mare there in one season than given in rewards to learned men since the time of Usher. All their productions in learning amount to perhaps a translation, or a few tracts in divinity; and all their productions in wit to just nothing at all. Why the plague, then, so fond of Ireland? Then, all at once, because you, my dear friend, and a few more who are exceptions to the general picture, have a residence there. This it is that gives me all the pangs I feel in separation. I confess I carry this spirit sometimes to the souring of the pleasures I at present possess. If I go to the opera, where Signora Columba pours out all the mazes of melody, I sit and sigh for Lissoy fireside, and Johnny Armstrong's 'Last Good-night' from Peggy Golden. If I climb Hampstead-hill, than where nature never exhibited a more magnificent prospect, I confess it fine; but then I had rather be placed on the little mount before Lissoy gate, and there take in, to me, the most pleasing horizon in nature.

"Before Charles came hither, my thoughts sometimes found refuge from severer studies among my friends in Ireland. I fancied strange revolutions at home; but I find it was the rapidity of my own motion that gave an imaginary one to objects really at rest. No alterations there. Some friends, he tells me, are still lean, but very rich; others very fat, but still very poor. Nay, all the news I hear of you is, that you sally out in visits among the neighbours, and sometimes make a migration from the blue bed to the brown. I could from my heart wish that you and she (Mrs. Hodson) and Lissoy and Ballymahon, and all of you, would fairly make a migration into Middlesex; though, upon second thoughts, this might be attended with a few inconveniences. Therefore, as the mountain will not come to Mohammed, why Mohammed shall go to the mountain; or, to speak plain English, as you cannot conveniently pay me a visit, if next summer I can contrive to be absent six weeks from London, I shall spend three of them among my friends in Ireland. But first, believe me, my design is purely to visit, and neither to out a figure nor levy contributions—neither to excite envy nor solicit favour; in fact, my circumstances are adapted to neither, I am to poor too to be gazed at, and too rich to need assistance."

## CHAP. IX.

Hackney authorship—Thoughts of literary suicide—return to Peckham—Oriental projects—Literary enterprise to raise funds—Letter to Edward Wells—To Robert Bryanton—Death of Uncle Contarine—Letter to Cousin Jane.

For some time Goldsmith continued to write miscellaneous for reviews and other periodical publications, but without making any decided hit, to use a technical term. Indeed, as yet he appeared destitute of the strong excitement of literary ambition, and wrote only on the spur of necessity and at the urgent importunity of his bookseller. His indolent and truant disposition, ever averse from labour and delighting in holiday, had to be scourged up to his task; still it was this very truant disposition which threw an unconscious charm over everything he wrote; bringing with it honeyed thoughts and pictured images which had sprung up in his mind in the sunny hours of idleness: these effusions, dashed off on compulsion in the exigency of the moment, were published anonymously; so that they made no collective impression on the public, and reflected no fame on the name of their author.

In an essay, published some time subsequently in the "Bee," Goldsmith adverts in his own humorous way to his impatience at the tardiness with which his desultory and acknowledged essays crept into notice. "I was once induced," says he, "to show my indignation against the public by discontinuing my efforts to please; and was bravely resolved, like Raleigh, to vex them by burning my manuscript in a passion. Upon reflection, however, I considered what set or body of people would be displeased at my rashness. The sun, after so sad an accident, might shine next morning as bright as usual; men might laugh and sing the next day, and transact business as before, and not a single creature feel any regret but myself. Instead of having Apollo in mourning or the Muses in a fit of the spleen—instead of having the learned world apostrophising at my untimely decease, perhaps all Grub-street might laugh at my fate, and self-approving dignity be unable to shield me from ridicule."

Circumstances occurred about this time to give a new direction to Goldsmith's hopes and schemes. Having resumed for a brief period the superintendence of the Peckham school during a fit of illness of Dr. Milner, that gentleman, in requital for his timely services, promised to use his influence with a friend, an East India director, to procure him a medical appointment in India.

There was every reason to believe that the influence of Dr. Milner would be effectual; but how was Goldsmith to find the ways and means of fitting himself out for a voyage to the Indies? In this emergency he was driven to a more extended exercise of the pen than he had yet attempted. His skirmishing among books as a reviewer, and his disputatious ramble among the schools and universities and literati of the continent, had filled his mind with facts and observations which he now set about digesting into a treatise of some magnitude, to be entitled "An Inquiry into the present State of Polite Learning in Europe." As the work grew on his hands his sanguine temper ran ahead of his labours. Feeling secure of success in England, he was anxious to forestall the piracy of the Irish press; for as yet the Union not having taken place, the English law of copyright did not extend to the other side of the Irish channel. He wrote, therefore, to his friends in Ireland, urging them to circulate his proposals for his contemplated work, and obtain subscriptions payable in advance—the money to be transmitted to a Mr. Bradley, an eminent bookseller in Dublin, who would give a receipt for it, and be accountable for the delivery of the books. The letters written by him on this occasion are worthy of copious citation, as being full of character and interest. One was to his relative and college intimate, Edward Wells,

who had studied for the bar, but was now living at ease on his estate at Roscommon. "You have quitted," writes Goldsmith, "the plan of life which you once intended to pursue, and given up ambition for domestic tranquillity. I cannot avoid feeling some regret that one of my few friends has declined a pursuit in which he had every reason to expect success. I have often let my fancy loose when you were the subject, and have imagined you gracing the bench, or thundering at the bar; while I have taken no small pride to myself, and whispered to all that I could come near that this was my cousin. Instead of this, you are merely content to be a happy man—to be esteemed by your acquaintances—to cultivate your paternal acres—to take unmolested a nap under one of your own hawthorns, or in Mrs. Wells's bed-chamber, which even a poet must confess is rather the more comfortable of the two. But, however your resolutions may be altered with regard to your situation in life, I persuade myself they are unalterable with respect to your friends in it. I cannot think the world has taken such entire possession of that heart (once so susceptible of friendship) as not to have left a corner there for a friend or two, but I flatter myself that even I have a place among the number. This I have a claim to from the similitude of our dispositions; or setting that aside, I can demand it as a right by the most equitable law of nature—I mean that of retaliation; for indeed you have more than your share in mine. I am a man of few professions; and yet at this very instant I cannot avoid the painful apprehension that my present professions (which speak not half my feelings) should be considered only as a pretext to cover a request, as I have a request to make. No, my dear Ned, I know you are too generous to think so, and you know me too proud to stoop to unnecessary insincerity. I have a request, it is true, to make; but as I know to whom I am a petitioner, I make it without diffidence or confusion. It is in short this—I am going to publish a book in London," &c. The residue of the letter specifies the nature of the request, which was merely to aid in circulating his proposals and obtaining subscriptions. The letter of the poor author, however, was unattended to and unacknowledged by the prosperous Mr. Wells, of Roscommon, though in after years he was proud to claim relationship to Dr. Goldsmith, when he had risen to celebrity.

Another of Goldsmith's letters was to Robert Bryanton, with whom he had long ceased to be in correspondence. "I believe," writes he "that they who are drunk, or out of their wits, fancy everybody else in the same condition. Mine is a friendship that neither distance nor time can efface, which is probably the reason that for the soul of me I can't avoid thinking yours of the same complexion; and yet I have many reasons for being of a contrary opinion, else why, in so long an absence, was I never made a partner in your concerns? To hear of your success would have given me the utmost pleasure; and a communication of your very disappointments would divide the uneasiness I too frequently feel for my own. Indeed, my dear Bob, you don't conceive how unkindly you have treated one whose circumstances afford him few prospects of pleasure, except those reflected from the happiness of his friends. However, since you have not let me hear from you, I have in some measure disappointed your neglect by frequently thinking of you. Every day or so I remember the calm anecdotes of your life, from the fireside to the easy chair; recal the various adventures that first cemented our friendship—the school, the college, or the tavern; preside in fancy over your cards; and am displeased at your bad play when the rubber goes against you, though not with all that agony of soul as when I was once your partner. Is it not strange that two of such like affections should be so much separated, and so differently employed as we are? You seem placed at the centre of fortune's wheel, and,

let it revolve ever so fast, are insensible of the motion. I seem to have been tied to the circumference, and whirled disagreeably round, as if on a whirligig."

He then runs into a whimsical and extravagant tirade about his future prospects—the wonderful career of fame and fortune that awaits him; and, after indulging in all kinds of humorous gasconades, concludes:—"Let me, then, stop my fancy to take a view of my future self—and, as the boys say, light down to see myself on horseback. Well, now that I am down, where the d—l is I! Oh gods! gods! here in a garret, writing for bread, and expecting to be dunned for a milk-score!"

He would on this occasion have doubtless written to his uncle Contarine, but that generous friend was sunk into a helpless, hopeless state, from which death soon released him.

Cut off thus from the kind co-operation of his uncle, he addressed a letter to his daughter Jane, the companion of his school-boy and happy days, now the wife of Mr. Lawder. The object was to secure her interest with her husband in promoting the circulation of his proposals. The letter is full of character.

"If you should ask," he begins, "why, in an interval of so many years, you never heard from me, permit me, madam, to ask the same question. I have the best excuse in recrimination. I wrote to Kilmore from Leyden in Holland, from Louvain in Flanders, and Rouen in France, but received no answer. To what could I attribute this silence but to displeasure or forgetfulness? Whether I was right in my conjecture I do not pretend to determine; but this I must ingenuously own, that I have a thousand times in my turn endeavoured to forget *them*, whom I could not but look upon as forgetting *me*. I have attempted to blot their names from my memory, and, I confess it, spent whole days in efforts to tear their image from my heart. Could I have succeeded, you would not now have been troubled with this renewal of a discontinued correspondence; but, as every effort the restless make to procure sleep serves but to keep them waking, all my attempts contributed to impress what I would forget deeper on my imagination. But this subject I would willingly turn from, and yet, 'for the soul of me,' I can't tell I have said all. I was, madam, when I discontinued writing to Kilmore, in such circumstance that all my endeavours to continue your regards might be attributed to wrong motives. My letters might be looked upon as the petitions of a beggar, and not the offerings of a friend: while all my professions, instead of being considered as the result of disinterested esteem, might be ascribed to venal insincerity. I believe, indeed, you had too much generosity to place them in such a light, but I could not bear even the shadow of such a suspicion. The most delicate friendships are always most sensible of the slightest invasion, and the strongest jealousy is ever attendant on the warmest regard. I could not—I own I could not—continue a correspondence in which every acknowledgment for past favours might be considered as an indirect request for future ones; and where it might be thought I gave my heart from a motive of gratitude alone, when I was conscious of having bestowed it on much more disinterested principles. It is true, this conduct might have been simple enough: but yourself must confess it was in character. Those who know me at all know that I have always been actuated by different principles from the rest of mankind, and while none regarded the interest of his friend more, no man on earth regarded his own less. I have often affected bluntness to avoid the imputation of flattery; have frequently seemed to overlook those merits too obvious to escape notice, and pretended disregard to those instances of good nature and good sense, which I could not fail tacitly to applaud; and all this lest I should be ranked

among the grinning tribe, who say, 'very true' to all that is said: who fill a vacant chair at a tea-table; whose narrow souls never moved in a wider circle than the circumference of a guinea; and who had rather be reckoning the money in your pocket than the virtue in your breast. All this, I say, I have done, and a thousand other very silly, though very disinterested, things in my time; and for all which no soul cares a farthing about me. \* \* \* Is it to be wondered that he should once in his life forget you, who has been all his life forgetting himself? However, it is probable you may one of these days see me turned into a perfect hunk, and as dark and intricate as a mouse-hole. I have already given my landlady orders for an entire reform in the state of my finances. I declaim again hot suppers, drink less sugar in my tea, and check my grate with brickbats. Instead of hanging my room with pictures, I intend to adorn it with maxims of frugality. Those will make pretty furniture enough, and won't be a bit too expensive; for I will draw them all out with my own hands, and my landlady's daughter shall frame them with the parings of my black waistcoat. Each maxim is to be inscribed on a clean sheet of paper, and wrote with my best pen; of which the following will serve as a specimen:—*Look sharp: Mind the main chance: Money is money now: If you have a thousand pounds you can put your hands by your sides, and say you are worth a thousand pounds every day of the year: Take a farthing from a hundred and it will be a hundred no longer.* Thus, which way soever I turn my eyes, they are sure to meet one of those friendly monitors; and as we are told of an actor who hung his room round with looking glass to correct the defects of his person, my apartments shall be furnished in a peculiar manner, to correct the errors of my mind. Faith! madam, I heartily wish to be rich, if it were only for this reason, to say without a blush how much I esteem you. But, alas! I have many a fatigue to encounter before that happy time comes, when your poor old simple friend may again give a loose to the luxuriance of his nature; sitting by Kilmore fireside, recount the various adventures of a hard-fought life—laugh over the follies of the day—join his flute to your harpsichord, and forget that ever he starved in those streets where Butler and Otway starved before him. And now I mention those great names—my Uncle! he is no more that soul of fire as when I once knew him. Newton and Swift grew dim with age as well as he. But what shall I say? His mind was too active an inhabitant not to disorder the feeble mansion of its abode; for the richest jewels soonest wear their sittings. Yet who but the fool would lament his condition! He now forgets the calamities of life. Perhaps indulgent Heaven has given him a foretaste of that tranquillity here which he so well deserves hereafter. But I must come to business; for business, as one of my maxims tells me, must be minded or lost. I am going to publish in London a book, entitled 'The present State of Taste and Literature in Europe.' The booksellers in Ireland republish every performance there without making the author any consideration. I would, in this respect, disappoint their avarice, and have all the profits of my labour to myself. I must, therefore, request Mr. Lawder to circulate among his friends and acquaintances a hundred of my proposals, which I have given the bookseller, Mr. Bradley, in Dame-street, directions to send to him. If, in pursuance of such circulation, he should receive any subscriptions, I entreat, when collected, they may be sent to Mr. Bradley as aforesaid, who will give a receipt, and be accountable for the work or a return of the subscription. If this request (which, if it be complied with, will in some measure be an encouragement to a man of learning) should be disagreeable or troublesome, I will not press it; for I would be the last man on earth to have my labours go a-begging; but if I know Mr. Lawder (and sure I ought

to know him), he will accept the employment with pleasure. All I can say—if he writes a book, I will get him two hundred subscribers, and these of the best wits in Europe. Whether this request is complied with or not, I shall not be uneasy; but there is one petition I must make to him and to you, which I solicit with the warmest ardour, and in which I cannot bear a refusal. I mean, dear madam, that I may be allowed to subscribe myself, your ever affectionate and obliged kinsman, OLIVER GOLDSMITH. Now see how I blot and blunder when I am asking a favour."

## CHAP. X.

Oriental appointment, and disappointment—Examination at the College of Surgeons—How to procure a suit of clothes—Fresh disappointment—A tale of distress—The suit of clothes in pawn—Punishment for doing an act of charity—Gaieties of Green Arbour Court—Letter to his brother—Life of Voltaire—Scroggins, an attempt at mock-heroic poetry.

While Goldsmith was yet labouring at his treatise, the promise made him by Dr. Milner was carried into effect, and he was actually appointed physician and surgeon to one of the factories on the coast of Coromandel. His imagination was immediately on fire with visions of oriental wealth and magnificence. It is true the salary did not exceed one hundred pounds, but then, as appointed physician, he would have the exclusive practice of the place, amounting to one thousand pounds per annum; with advantages to be derived from trade and from the high interest of money—twenty per cent.; in a word, for once in his life the road to fortune lay broad and straight before him.

Hitherto, in his correspondence with his friends, he had said nothing of his India scheme; but now he imparted to them his brilliant prospects, urging the importance of their circulating his proposals and obtaining him subscriptions and advances on his forthcoming work, to furnish funds for his outfit.

In the meantime he had to task that poor drudge, his muse, for present exigencies. Ten pounds were demanded for his appointment-warrant. Other expenses pressed hard upon him. Fortunately, though as yet unknown to fame, his literary capability was known to "the trade," and the coinage of his brain passed current in Grub-street. Archibald Hamilton, proprietor of the "Critical Review," the rival to that of Griffiths, readily made him a small advance on receiving three articles for his periodical. His purse thus slenderly replenished, Goldsmith paid for his warrant; wiped off the score of his milkmaid; abandoned his garret, and moved into a shabby first-floor in a forlorn court near the Old Bailey; there to await the time of his migration to the magnificent coast of Coromandel.

Alas! poor Goldsmith! ever doomed to disappointment. Early in the gloomy month of November—that month of fog and despondency in London—he learnt the shipwreck of his hope. The great Coromandel enterprise fell through—or rather, the post promised to him was transferred to some other candidate. The cause of this disappointment it is now impossible to ascertain. The death of his *quasi* patron, Dr. Milner, which happened about this time, may have had some effect in producing it; or there may have been some heedlessness and blundering on his own part, or some obstacle arising from his insuperable indigence; whatever may have been the cause, he never mentioned it, which gives some ground to surmise that he himself was to blame. His friends learnt with surprise that he had suddenly relinquished his appointment to India, about which he had raised such sanguine expectations: some accused him of fickleness and caprice; others supposed him unwilling to tear himself from the growing fascinations of the literary society of London.

In the meantime, cut down in his hopes and humiliated in his pride by the failure of his Coromandel scheme, he sought, without consulting his friends, to be examined at the College of Physicians for the humble situation of hospital mate. Even here poverty stood in his way. It was necessary to appear in a decent garb before the examining committee; but how was he to do so? He was literally out of elbows as well as out of cash. Here again the muse, so often jilted and neglected by him, came to his aid. In consideration of four articles furnished to the "Monthly Review," Griffiths, his old task-master, was to become security to the tailor for a suit of clothes. Goldsmith said he wanted them but for a single occasion, on which depended his appointment to a situation in the army; as soon as that temporary purpose was served they would either be returned or paid for. The books to be reviewed were accordingly lent to him—the muse was again set to his compulsory drudgery—the articles were scribbled off and sent to the bookseller, and the clothes came in due time from the tailor.

From the records of the College of Surgeons, it appears that Goldsmith underwent his examination at Surgeons' Hall on the 21st December, 1758. Either from a confusion of mind incident to sensitive and imaginative persons on such occasions, or from a real want of surgical science, which last is extremely probable, he failed in his examination, and was rejected as unqualified. The effect of such rejection was to disqualify him for every branch of public service, though he might have claimed a re-examination, after the interval of a few months devoted to further study. Such a re-examination he never attempted, nor did he ever communicate his discomfiture to any of his friends.

On Christmas-day, but four days after his rejection by the College of Surgeons, while he was suffering under the mortification of defeat and disappointment, and hard pressed for means of subsistence, he was surprised by the entrance into his room of the poor woman of whom he hired his wretched apartment, and to whom he owed some small arrears of rent. She had a piteous tale of distress, and was clamorous in her afflictions. Her husband had been arrested in the night for debt, and thrown into prison. This was too much for the quick feelings of Goldsmith; he was ready at any time to help the distressed, but in this instance he was himself in some measure a cause of the distress. What was to be done? He had no money, it is true; but there hung the new suit of clothes in which he had stood his unlucky examination at Surgeons' Hall. Without giving himself time for reflection, he sent it off to the pawnbroker's, and raised thereon a sufficient sum to pay off his own debt, and to release his landlord from prison.

Under the same pressure of penury and despondency, he borrowed from a neighbour a pittance to relieve his immediate wants, leaving as a security the books which he had recently reviewed. In the midst of these straits and harassments, he received a letter from Griffiths, demanding in peremptory terms the return of the clothes and books, or immediate payment for the same. It appears that he had discovered the identical suit at the pawnbroker's. The reply of Goldsmith is not known; it was out of his power to furnish either the clothes or the money; but he probably offered once more to make the muse stand his bail. His reply only increased the ire of the wealthy man of trade, and drew from him another letter, still more harsh than the first, using the epithets of knave and sharper, and containing threats of prosecution and a prison.

The following letter from poor Goldsmith gives the most touching picture of an inconsiderate but sensitive man, harassed by care, stung by humiliations, and driven almost to despondency:—

"SIR,—I know of no misery but a jail to which my own imprudences and your letter seem to point. I have

seen it inevitable these three or four weeks, and, by heavens! request it as a favour—as a favour that may prevent something more fatal. I have been some years struggling with a wretched being—with all that contempt and indigence brings with it—with all those passions which make contempt unsupportable. What, then, has a jail that is formidable? I shall at least have the society of wretches, and such is to me true society. I tell you, again and again, that I am neither able nor willing to pay you a farthing, but I will be punctual to any appointment you or the tailor shall make; thus far, at least, I do not act the sharper, since unable to pay my own debts one way, I would generally give some security another. No, sir; had I been a sharper—had I been possessed of less good-nature and native generosity, I might surely now have been in better circumstances.

"I am guilty, I own, of meannesses which poverty unavoidably brings with it: my reflections are filled with repentance for my imprudence, but not with any remorse for being a villain; that may be a character you unjustly charge me with. Your books, I can assure you, are neither pawned nor sold, but in the custody of a friend, from whom my necessities obliged me to borrow some money: whatever becomes of my person, you shall have them in a month. It is very possible both the reports you have heard and your own suggestions may have brought you false information with respect to my character; it is very possible that the man whom you now regard with detestation may inwardly burn with grateful resentment. It is very possible that, upon a second perusal of the letter I sent you, you may see the workings of a mind strongly agitated with gratitude and jealousy. If such circumstances should appear, at least spare invective till my book with Mr. Dodsley shall be published, and then, perhaps, you may see the bright side of a mind, when my professions shall not appear the dictates of necessity, but of choice.

"You seem to think Dr. Milner knew me not. Perhaps so; but he was a man I shall ever honour; but I have friendships only with the dead! I ask pardon for taking up so much time; nor shall I add to it by any other professions than that I am, sir, your humble servant,

"OLIVER GOLDSMITH.

"P.S.—I shall expect impatiently the result of your resolutions."

The dispute between the poet and the publisher was afterward imperfectly adjusted, and it would appear that the clothes were paid for by a short compilation advertised by Griffiths in the course of the following month; but the parties were never really friends afterward, and the writings of Goldsmith were harshly and unjustly treated in the "Monthly Review."

We have given the preceding anecdote in detail, as furnishing one of the many instances in which Goldsmith's prompt and benevolent impulses outran all prudent forecast, and involved him in difficulties and disgraces which a more selfish man would have avoided. The pawning of the clothes, charged upon him as a crime by the grinding bookseller, and apparently admitted by him as one of "the meannesses which poverty unavoidably brings with it," resulted, as we have shown, from a tenderness of heart and generosity of hand in which another man would have gloried; but these were such natural elements with him that he was unconscious of their merit. It is a pity that wealth does not oftener bring such "meannesses" in its train.

And now let us be indulged in a few particulars about these lodgings in which Goldsmith was guilty of this thoughtless act of benevolence. They were in a very shabby house, No. 12, Green-arbour-court, between the Old Bailey and Fleet Market. An old woman was still living in 1820, who was a relative of the identical landlady whom Goldsmith relieved by the money received from the pawnbroker. She was a child

about seven years of age at the time that the poet rented his apartment of her relative, and used frequently to be at the house in Green-arbour-court. She was drawn there, in a great measure, by the good-humored kindness of Goldsmith, who was always exceedingly fond of the society of children. He used to assemble those of the family in his room, give them cakes and sweetmeats, and set them dancing to the sound of his flute. He was very friendly to those around him, and cultivated a kind of intimacy with a watchmaker in the court, who possessed much native wit and humour. He passed most of the day, however, in his room, and only went out in the evenings. His days were no doubt devoted to the drudgery of the pen, and it would appear that he occasionally found the booksellers urgent taskmasters. On one occasion a visitor was shown up to his room, and immediately their voices were heard in high altercation, and the key was turned within the lock. The landlady, at first, was disposed to go to the assistance of her lodger; but a calm succeeding, she forbore to interfere.

Late in the evening the door was unlocked; a supper ordered by the visitor from a neighbouring tavern, and Goldsmith and his intrusive guest finished the evening in great good-humour. It was probably his old taskmaster Griffiths, whose press might have been waiting, and who found no other mode of getting a stipulated task from Goldsmith than by locking him in and staying by him until it was finished.

But we have a more particular account of these lodgings in Green-arbour-court from the Rev. Thomas Percy, afterward Bishop of Dromore, and celebrated for his relics of ancient poetry, his beautiful ballads, and other works. During an occasional visit to London he was introduced to Goldsmith by Grainger, and ever after continued one of his most steadfast and valued friends. The following is his description of the poet's squalid apartment:—"I called on Goldsmith at his lodgings in March, 1759, and found him writing his 'Inquiry,' in a miserable, dirty-looking room, in which there was but one chair; and when, from civility, he resigned it to me, he himself was obliged to sit in the window. While we were conversing together some one tapped gently at the door, and being desired to come in, a poor, ragged little girl, of a very becoming demeanour, entered the room, and, dropping a courtsey, said, 'My mamma sends her compliments, and begs the favour of you to lend her a chamber-pot full of coals.'"

We are reminded in this anecdote of Goldsmith's picture of the lodgings of Beau Tibbs, and of the peep into the secrets of a make-shift establishment given to a visitor by the blundering old Scotchwoman.

"By this time we were arrived as high as the stairs would permit us to ascend, till we came to what he was facetiously pleased to call the first-floor down the chimney; and knocking at the door, a voice from within demanded 'Who's there?' My conductor answered that it was him. But this not satisfying the querist, the voice again repeated the demand, to which he answered louder than before; and now the door was opened by an old woman with cautious reluctance.

"When we got in, he welcomed me to his house with great ceremony; and, turning to the old woman, asked where was her lady. 'Good troth,' replied she, in a peculiar dialect, 'she's washing your twa shirts at the next door, because they have taken an oath against lending the tub any longer.' 'My two shirts!' cried he, in a tone that faltered with confusion; 'what does the idiot mean?' 'I ken what I mean weel enough,' replied the other; 'she's washing your twa shirts at the next door, because—' Fire and fury! no more of thy stupid explanations,' cried he; 'go and inform her we have company. Were that Scotch hag to be for ever in my family, she would never learn politeness, nor forget that absurd poisonous accent of hers, or testify the smallest

specimen of breeding or high life; and yet it is very surprising too, as I had her from a Parliament man, a friend of mine from the Highlands, one of the politest men in the world; but that's a secret."

Let us linger a little in Green-arbour-court—a place consecrated by the genius and the poverty of Goldsmith, but recently obliterated in the course of modern improvements. The writer of this memoir visited it not many years since on a literary pilgrimage, and may be excused for repeating a description of it which he has heretofore inserted in another publication. "It then existed in its pristine state, and was a small square of tall and miserable houses, the very intestines of which seemed turned inside out, to judge from the old garments and frippery that fluttered from every window. It appeared to be a region of washerwomen, and lines were stretched across the little square, on which clothes were dangling to dry.

"Just as we entered the square a scuffle took place between two viragoes about a disputed right to a wash-tub, and immediately the whole community was in a hubbub. Heads in mob caps popped out of every window, and such a clamour of tongues ensued that I was fain to stop my ears. Every Amazon took part with one or other of the disputants, and brandished her arms, dripping with soapsuds, and fired away from her window as from the embrasure of a fortress; while the screams of children nestled and cradled in every procreant chamber of this hive, waking with the noise, set up their shrill pipes to swell the general concert."

While in these forlorn quarters, suffering under extreme depression of spirits, caused by his failure at Surgeons' Hall, the disappointment of his hopes, and his harsh collisions with Griffiths, Goldsmith wrote the following letter to his brother Henry, some parts of which are most touchingly mournful.

"DEAR SIR,—Your punctuality in answering a man whose trade is writing, is more than I had reason to expect; and yet you generally see me fill a whole sheet, which is all the recompense I can make for being so frequently troublesome. The behaviour of Mr. Wells and Mr. Lawder is a little extraordinary. However, their answering neither you nor me is a sufficient indication of their disliking the employment which I assigned them. As their conduct is different from what I had expected, so I have made an alteration in mine. I shall, the beginning of next month, send over two hundred and fifty books,\* which are all that I fancy can be well sold among you, and I would have you make some distinction in the persons who have subscribed. The money, which will amount to sixty pounds, may be left with Mr. Bradley as soon as possible. I am not certain but I shall quick'y have occasion for it.

"I have met with no disappointment with respect to my East India voyage, nor are my resolutions altered; though, at the same time, I must confess it gives me some pain to think that I am almost beginning the world at the age of thirty-one. Though I never had a day's sickness since I saw you, yet I am not that strong, active man you once knew me. You scarcely can conceive how much eight years of disappointment, anguish, and study have worn me down. If I remember right you are seven or eight years older than me, yet I dare venture to say, that if a stranger saw us both he would pay me the honours of seniority. Imagine to yourself a pale, melancholy visage, with two great wrinkles between the eyebrows, with an eye disgustingly severe, and a big wig; and you may have a perfect picture of my present appearance. On the other hand, I conceive you as perfectly sleek and healthy, passing many a happy day among your own children, or those who knew you a child.

"Since I knew what it was to be a man, this is a

pleasure I have not known. I have passed my days among a parcel of cool, designing beings, and have contracted all their suspicious manner in my own behaviour. I should actually be as unfit for the society of my friends at home, as I detest that which I am obliged to partake of here. I can now neither partake of the pleasure of a revel, nor contribute to raise its jollity. I can neither laugh nor drink—have contracted a hesitating, disagreeable manner of speaking, and a visage that looks ill-nature itself; in short, I have thought myself into a settled melancholy, and an utter disgust of all that life brings with it. Whence this romantic turn that all our family are possessed with? Whence this love for every place and every country but that in which we reside—for every occupation but our own? This desire of fortune, and yet this eagerness to dissipate? I perceive, my dear sir, that I am at intervals for indulging this splenetic manner, and following my own taste regardless of yours.

"The reasons you have given me for breeding up your son a scholar are judicious and convincing; I should, however, be glad to know for what particular profession he is designed. If he be assiduous and divested of strong passions (for passions in youth always lead to pleasure), he may do very well in your college; for it must be owned that the industrious poor have good encouragement there—perhaps better than in any other in Europe. But if he has ambition, strong passions, and an exquisite sensibility of contempt, do not send him there, unless you have no other trade for him but your own. It is impossible to conceive how much may be done by proper education at home. A boy, for instance, who understands perfectly well Latin, French, arithmetic, and the principles of the civil law, and can write a fine hand, has an education that may qualify him for any undertaking; and these parts of learning should be carefully inculcated, let him be designed for whatever calling he will.

"Above all things, let him never touch a romance or novel; these paint beauty in colours more charming than nature, and describe happiness that man never tastes. How delusive, how destructive are those pictures of consummate bliss! They teach the youthful mind to sigh after beauty and happiness that never existed—to despise the little good which fortune has mixed in our cup, by expecting more than she ever gave; and, in general, take the word of a man who has seen the world, and who has studied human nature more by experience than precept—take my word for it, I say, that books teach us very little of the world. The greatest merit in a state of poverty would only serve to make the possessor ridiculous—may distress, but cannot relieve him. Frugality, and even avarice, in the lower orders of mankind are true ambition. These afford the only ladder for the poor to rise to preferment. Teach then, my dear sir, to your son—thrift and economy. Let his poor wandering uncle's example be placed before his eyes. I had learned from books to be disinterested and generous, before I was taught from experience the necessity of being prudent. I had contracted the habits and notions of a philosopher, while I was exposing myself to the approaches of insidious cunning; and often by being even with my narrow finances, charitable to excess, I forgot the rules of justice, and placed myself in the very situation of the wretch who thanked me for my bounty. When I am in the remotest part of the world, tell him this, and perhaps he may improve from my example. But I find myself again falling into my gloomy habits of thinking.

"My mother, I am informed, is almost blind; even though I had the utmost inclination to return home, under such circumstances I could not, for to behold her in distress without a capacity of relieving her from it would add much to my splenetic habit. Your last letter was much too short; it should have answered some

\* The "Inquiry into Polite Literature." His previous remarks apply to the subscription.

queries I had made in my former. Just sit down as I do, and write forward until you have filled all your paper. It requires no thought, at least from the ease with which my own sentiments rise when they are addressed to you. For believe me, my head has no share in all I write; my heart dictates the whole. Pray give my love to Bob Bryanton, and entreat him from me not to drink. My dear sir, give me some account about poor Jenny.\* Yet her husband loves her: if so, she cannot be unhappy.

"I know not whether I should tell you—yet why should I conceal these trifles, or, indeed, anything from you? There is a book of mine will be published in a few days, the life of a very extraordinary man—no less than the great Voltaire. You know already by the title that it is no more than a catchpeuny. However, I spent but four weeks on the whole performance, for which I received twenty pounds. When published, I shall take some method of conveying it to you, unless you may think it dear of the postage, which may amount to four or five shillings. However, I fear you will not find an equivalent of amusement.

"Your last letter, I repeat it, was too short; you should have given me your opinion of the design of the heroical poem which I sent you. You remember, I intended to introduce the hero of the poem as lying in a paltry alehouse. You may take the following specimen of the manner, which I flatter myself is quite original. The room in which he lies may be described somewhat in this way:—

The window, patch'd with paper, lent a ray  
That feebly show'd the state in which he lay;  
The sanded floor, that grits beneath the tread,  
The humid wall with paltry pictures spread;  
The game of goose was there exposed to view,  
And the twelve rules the royal martyr drew;  
The Seasons, framed with listing, found a place,  
And Prussia's monarch show'd his lamp-black face.  
The morn was cold; he views with keen desire  
A rusty grate, unconscious of a fire;  
An unpaid reckoning on the frieze was scored,  
And five crack'd teacups dress'd the chimney-board.

"And now imagine, after his soliloquy, the landlord to make his appearance in order to dun him for the reckoning:—

Not with that face, so servile and so gay,  
That welcomes every stranger that can pay;  
With sulky eye he smoked the patient man,  
Then pull'd his breeches tight, and thus began,†

"All this is taken, you see, from nature. It is a good remark of Montaigne's, that the wisest men often have friends with whom they do not care how much they play the fool. Take my present follies as instances of my regard. Poetry is a much easier and more agreeable species of composition than prose; and, could a man live by it, it were not unpleasant employment to be a poet. I am resolved to leave no space, though I should fill it up only by telling you, what you very well know already—I mean that I am your most affectionate friend and brother,

"OLIVER GOLDSMITH."

The "Life of Voltaire," alluded to in the latter part of the preceding letter, was the literary job undertaken to satisfy the demands of Griffiths. It was to have preceded a translation of the *Henriade*, by Ned Purdon, Goldsmith's old schoolmate, who starved rather than lived by the exercise of his pen, and often tasked Goldsmith's scanty means to relieve his hunger. His miserable career was summed up by our poet in the following lines, written some years after the time we are treat-

\* His sister, Mrs. Johnston; her marriage, like that of Mrs. Hodson, was private, but in pecuniary matters much less fortunate.

† The projected poem, of which the above are specimens, appears never to have been completed.

ing of, on hearing that he had suddenly dropped dead in Smithfield:—

Here lies poor Ned Purdon, from misery freed,  
Who long was a bookseller's hack;  
He led such a damnable life in this world,  
I don't think he'll wish to come back.

The memoir and translation, though advertised to form a volume, were not published together, but appeared separately in a magazine.

As to the heroical poem, also cited in the foregoing letter, it appears to have perished in embryo. Had it been brought to maturity we should have had further traits of autobiography; the room already described was probably his own squalid quarters in Green-arbour-court; and in a subsequent morsel of the poem we have the poet himself, under the euphonious name of Scroggin:—

Where the Red Lion peering o'er the way,  
Invites each passing stranger that can pay;  
Where Calvert's butt and Parson's black champagne  
Regale the drabs and bloods of Drury Lane:  
There, in a lonely room, from bailiffs snug,  
The muse found Scroggin stretch'd beneath a rug;  
A nightcap deck'd his brow instead of bay,  
A cap by night, a stocking all the day.

It is to be regretted that this poetical conception was not carried out; like the author's other writings, it might have abounded with pictures of life and touches of nature drawn from his own observation and experience, and mellowed by his own humane and tolerant spirit; and might have been a worthy companion, or rather contrast, to his "Traveller" and "Deserted Village," and have remained in the language a first-rate specimen of the mock-heroic.

## CHAP. XI.

Publication of "The Inquiry"—Attacked by Griffiths' Review—Kenrick, the literary Ishmaelite—Periodical literature—Goldsmith's *Essays*—Garriek as a nazer—Smollett and his schemes—Change of lodgings—The Robin Hood club.

Towards the end of March, 1759, the treatise on which Goldsmith had laid so much stress, on which he at one time had calculated to defray the expenses of his outfit to India, and to which he had adverted in his correspondence with Griffiths, made its appearance. It was published by the Dodsleys, and entitled "An Inquiry into the Present State of Polite Learning in Europe."

In the present day, when the whole field of contemporary literature is so widely surveyed and amply discussed, and when the current productions of every country are constantly collated and ably criticised, a treatise like that of Goldsmith would be considered as extremely limited and unsatisfactory; but at that time it possessed novelty in its views and wideness in its scope, and being endued with the peculiar charm of style inseparable from the author, it commanded public attention and a profitable sale. As it was the most important production that had yet come from Goldsmith's pen, he was anxious to have the credit of it; yet it appeared without his name on the title-page. The authorship, however, was well-known throughout the world of letters, and the author had now grown into sufficient literary importance to become an object of hostility to the underlings of the press. One of the most virulent attacks upon him was in a criticism on this treatise, and appeared in the "Monthly Review," to which he himself had been recently a contributor. It slandered him as a man, while it decried him as an author, and accused him by innuendo of "labouring under the infamy of having, by the vilest and meanest actions, forfeited all pretensions to honour and honesty," and of practising "those acts which bring the sharper to the cart's-tail or the pillory."

It will be remembered that the Review was owned by Griffiths the bookseller, with whom Goldsmith had recently had a misunderstanding. The criticism, therefore, was no doubt dictated by the lingerings of resentment; and the imputations upon Goldsmith's character for honour and honesty, and the vile and mean actions hinted at, could only allude to the unfortunate pawning of the clothes. All this, too, was after Griffiths had received the affecting letters from Goldsmith, drawing a picture of his poverty and perplexities, and after the latter had made him a literary compensation. Griffiths, in fact, was sensible of the falsehood and extravagance of the attack, and tried to exonerate himself by declaring that the criticism was written by a person in his employ; but we see no difference in atrocity between him who wields the knife and him who hires the cut-throat. It may be well, however, in passing, to bestow our mite of notoriety upon the miscreant who launched the slander. He deserves it for a long course of dastardly and venomous attacks, not merely upon Goldsmith, but upon most of the successful authors of the day. His name was Kenrick. He was originally a mechanic, but possessing some degree of talent and industry, applied himself to literature as a profession. This he pursued for many years, and tried his hand in every department of prose and poetry; he wrote plays and satires, philosophical tracts, critical dissertations, and works on philology; nothing from his pen ever rose to first-rate excellence, or gained him a popular name, though he received from some university the degree of Doctor of Laws. Dr. Johnson characterised his literary career in one short sentence: "Sir, he is one of the many who have made themselves *public* without making themselves *known*."

Soured by his own want of success, jealous of the success of others, his natural irritability of temper increased by habits of intemperance, he at length abandoned himself to the practice of reviewing, and became one of the Ishmaelites of the press. In this, his malignant bitterness soon gave him a notoriety which his talents had never been able to attain. We shall dismiss him for the present with the following sketch of him, by the hand of one of his contemporaries:—

Dreaming of genius which he never had,  
Half wit, half fool, half critic, and half mad;  
Seizing, like Shirley, on the poet's lyre,  
With all his rage, but not one spark of fire;  
Eager for slaughter, and resolved to tear  
From others' brows that wreath he must not wear—  
Next Kenrick came, all furious and replete  
With brandy, malice, pertness, and conceit;  
Unskill'd in classic lore, through envy blind  
To all that's beautiful, learned, or refined;  
For faults alone, behold this savage prowls,  
With reason's offal glut his ravening soul;  
Pleased with his prey, its inmost blood he drinks,  
And mumbles, paws, and turns it—till it stinks.

The British press about this time was extravagantly fruitful of periodical publications. That "oldest inhabitant," the "Gentleman's Magazine," almost coeval with St. John's Gate, which graced its title-page, had long been elbowed by magazines and reviews of all kinds; Johnson's "Rambler" had introduced the fashion of periodical essays, which he had followed up in his "Adventurer" and "Idler." Imitations had sprung up on every side, under every variety of name; until British literature was entirely overrun by a weedy and transient efflorescence. Many of these rival periodicals choked each other almost at the outset, and few of them have escaped oblivion.

Goldsmith wrote for some of the most successful, such as "The Bee," "The Busy Body," and "The Lady's Magazine." His essays, though characterised by his delightful style, his pure, benevolent morality, and his mellow, unobtrusive humour, did not produce equal effect at first with more garish writings of infinitely less

value; they did not "strike," as it is termed; but they had that rare and enduring merit which rises in estimation on every perusal. They gradually stole upon the heart of the public, were copied into numerous contemporary publications, and now they are garnered up among the choice productions of British literature.

In his "Inquiry into the State of Polite Learning," Goldsmith had given offence to David Garrick, at that time the autocrat of the drama, and was doomed to experience its effects. A clamour had been raised against Garrick for exercising a despotism over the stage, and bringing forward nothing but old plays, to the exclusion of original productions. Walpole joined in this charge "Garrick," said he, "is treating the town as it deserves and likes to be treated, with scenes, fire-works, and his own writings. A good new play I never expect to see more; nor have seen since the 'Provoked Husband,' which came out when I was at school." Goldsmith, who was extremely fond of the theatre, and felt the evils of this system, inveighed in his treatise against the wrongs experienced by authors at the hands of managers. "Our poet's performance," said he, "must undergo a process truly chemical before it is presented to the public. It must be tried in the manager's fire—strained through a licenser—suffer from repeated corrections, till it may be mere *caput mortuum* when it arrives before the public." Again—"Getting a play on even in three or four years is a privilege reserved only for the happy few who have the arts of courting the manager as well as the muse—who have adulation to please his vanity, powerful patrons to support their merit, or money to indemnify disappointment. Our Saxon ancestors had but one name for a wit and a witch. I would not dispute the propriety of uniting those characters then; but the man who under present discouragements ventures to write for the stage, whatever claim he may have to the appellation of a wit, has at least no right to be called a conjuror." But a passage which perhaps touched more sensibly than all the rest on the sensibilities of Garrick was the following:—

"I have no particular spleen against the fellow who sweeps the stage with the broom, or the hero who brushes it with his train. It were a matter of indifference to me whether our heroines are in keeping or our candle-snuffers burn their fingers, did not such make a great part of public care and polite conversation. Our actors assume all that state off the stage which they do on it; and, to use an expression borrowed from the green-room, every one is *up* in his part. I am sorry to say it, they seem to forget their real characters."

These strictures were considered by Garrick as intended for himself, and they were ranking in his mind when Goldsmith waited upon him, and solicited his vote for the vacant secretaryship of the Society of Arts, of which the manager was a member. Garrick, puffed up by his dramatic renown and his intimacy with the great, and knowing Goldsmith only by his budding reputation, may not have considered him of sufficient importance to be conciliated. In reply to his solicitations, he observed that he could hardly expect his friendly exertions after the unprovoked attack he had made upon his management. Goldsmith replied that he had indulged in no personalities, and had only spoken what he believed to be the truth. He made no further apology nor application, failed to get the appointment, and considered Garrick his enemy. In the second edition of this treatise he expunged or modified the passages which had given the manager offence; but though the author and actor became intimate in after years, this false step at the outset of their intercourse was never forgotten.

About this time Goldsmith engaged with Dr. Smollett, who was about to launch the British Magazine. Smollett was a complete schemer and speculator in literature, and intent upon enterprises that had money rather than reputation in view. Goldsmith has a good-humoured

hit at his propensity in one of his papers in the "Bee," in which he represents Johnson, Hume, and others taking seats in the stage-coach bound for Fane, while Smollett prefers that destined for Riches.

Another prominent employer of Goldsmith was Mr. John Newbery, who engaged him to contribute occasional essays to a newspaper entitled the "Public Ledger," which made its first appearance on the 12th of January, 1760. His most valuable and characteristic contributions to this paper were his "Chinese Letters," subsequently modified into the "Citizen of the World." These lucubrations attracted general attention; they were reprinted in the various periodical publications of the day, and met with great applause. The name of the author, however, was as yet but little known.

Being now easier in circumstances, and in the receipt of frequent sums from the booksellers, Goldsmith, about the middle of 1760, emerged from his dismal abode in Green-arbour-court, and took respectable apartments in Wine-office-court, Fleet-street.

Still he continued to look back with considerate benevolence to the poor hostess whose necessities he had relieved by pawning his gala coat, for we are told that "he often supplied her with food from his own table, and visited her frequently with the sole purpose to be kind to her."

He now became a member of a debating club, called the "Robin Hood," which used to meet near Temple Bar, and in which Burke, while yet a Temple student, had first tried his powers. Goldsmith spoke here occasionally, and is recorded in the Robin Hood archives as "a candid disputant, with a clear head and an honest heart, though coming but seldom to the society." His relish was for clubs of a more social, jovial nature, and he was never fond of argument. An amusing anecdote is told of his first introduction to the club, by Samuel Derrick, an Irish acquaintance of some humour. On entering, Goldsmith was struck with the self-important appearance of the chairman, ensconced in a large gilt chair. "This," said he, "must be the Lord-Chancellor at least." "No, no," replied Derrick, "he's only master of the rolls."—"The chairman was a baker.

## CHAP. XII.

New lodgings—Visits of ceremony—Hangers-on—Pilkington and the white mouse—Introduction to Dr. Johnson—Davies and his book-shop—Pretty Mrs. Davies—Foote and his projects—Criticism of the cudgel.

In his new lodgings in Wine-office-court Goldsmith began to receive visits of ceremony, and to entertain his literary friends. Among the latter he now numbered several names of note, such as Guthrie, Murphy, Christopher Smart, and Bickerstaff. He had also a numerous class of hangers-on, the small fry of literature; who, knowing his almost utter incapacity to refuse a pecuniary request, were apt, now that he was considered flush, to levy continual taxes upon his purse.

Among others, one Pilkington, an old college acquaintance, but now a shifting adventurer, duped him in the most ludicrous manner. He called on him with a face full of perplexity. A lady of the first rank having an extraordinary fancy for curious animals, for which she was willing to give enormous sums, he had procured a couple of white mice to be forwarded to her from India. They were actually on board of a ship in the river. Her grace had been apprised of her arrival, and was all impatience to see them. Unfortunately he had no cage to put them in, nor clothes to appear in before a lady of her rank. Two guineas would be sufficient for his purpose, but where were two guineas to be procured?

The simple heart of Goldsmith was touched; but, alas! he had but half-a-guinea in his pocket. It was unfor-

tunate, but, after a pause, his friend suggested, with some hesitation, "that money might be raised upon his watch; it would be but the loan of a few hours." So said, so done; the watch was delivered to the worthy Mr. Pilkington to be pledged at a neighbouring pawnbroker's; but nothing further was ever seen of him, the watch, or the white mice. The next that Goldsmith heard of the poor shifting scapegrace, he was on his death-bed, starving with want; upon which, forgetting or forgiving the trick he had played upon him, he sent him a guinea. Indeed, he used often to relate with great humour the foregoing anecdote of his credulity, and was ultimately in some degree indemnified, by its suggesting to him the amusing little story of Prince Boubenmin and the White Mouse in the "Citizen of the World."

In this year Goldsmith became personally acquainted with Dr. Johnson, toward whom he was drawn by strong sympathies, though their natures were widely different. Both had struggled from early life with poverty, but had struggled in different ways. Goldsmith—buoyant, heedless, sanguine, tolerant of evils and easily pleased—had shifted along by any temporary expedient; cast down at every turn, but rising again with indomitable good humour, and still carried forward by his talent of hoping. Johnson—melancholy and hypochondriacal, and prone to apprehend the worst, yet sternly resolute to battle with and conquer it—had made his way doggedly and gloomily, but with a noble principle of self-reliance and a disregard of foreign aid. Both had been irregular at college—Goldsmith, as we have shown, from the levity of his nature and his social and convivial habits; Johnson, from his acerbity and gloom. When in after life the latter heard himself spoken of as gay and frolicsome at college, because he had joined in some riotous excesses there, "Ah, sir!" replied he, "I was mad and violent. It was bitterness which they mistook for frolic. *I was miserably poor, and I thought to fight my way by my literature and my wit.* So I disregarded all power and all authority."

Goldsmith's poverty was never accompanied by bitterness; but neither was it accompanied by the guardian pride which kept Johnson from falling into the degrading shifts of poverty. Goldsmith had an unfortunate facility at borrowing, and helping himself along by the contributions of his friends; no doubt trusting, in his hopeful way, of one day making retribution. Johnson never hoped, and therefore never borrowed. In his sternest trials he proudly bore the ills he could not master. In his youth, when some unknown friend, seeing his shoes completely worn out, left a new pair at his chamber door, he disdained to accept the boon, and threw them away.

Though, like Goldsmith, an immethodical student, he had imbibed deeper draughts of knowledge, and made himself a riper scholar. While Goldsmith's happy constitution and genial humours carried him abroad into sunshine and enjoyment, Johnson's physical infirmities and mental gloom drove him upon himself—to the resources of reading and meditation; threw a deeper though darker enthusiasm into his mind, and stored a retentive memory with all kinds of knowledge.

After several years of youth passed in the country as usher, teacher, and an occasional writer for the press, Johnson, when twenty-eight years of age, came up to London with a half-written tragedy in his pocket; and David Garrick, late his pupil, and several years his junior, as a companion—both poor and penniless—both, like Goldsmith, seeking their fortunes in the metropolis. "We rode and tied," said Garrick sportively in after years of prosperity, when he spoke of their humble way-faring. "I came to London," said Johnson, "with twopence-halfpenny in my pocket." "Eh, what's that you say?" cried Garrick, "with twopence-halfpenny in your pocket?" "Why, yes; I came with twopence-halfpenny in my pocket, and thou, Davy, with but three-halfpence

in thine." Nor was there much exaggeration in the picture; for so poor were they in purse and credit, that after their arrival they had with difficulty raised five pounds, by giving their joint note to a bookseller in the Strand.

Many, many years had Johnson gone on obscurely in London, "fighting his way by his literature and his wit;" enduring all the hardships and the miseries of a Grub-street writer: so destitute at one time, that he and Savage the poet had walked all night about St. James's-square, both too poor to pay for a night's lodging, yet both full of poetry and patriotism, and determined to stand by their country; so shabby in dress at another time, that when he dined at Cave's, his bookseller, when there was prosperous company, he could not make his appearance at table, but had his dinner handed to him behind a screen.

Yet through all the long and dreary struggle, often diseased in mind as well as in body, he had been resolutely self-dependent, and proudly self-respectful; he had fulfilled his college vow—he had "fought his way by his literature and his wit." His "Rambler" and "Idler" had made him the great moralist of the age, and his "Dictionary and History of the English Language," that stupendous monument of individual labour, had excited the admiration of the learned world. He was now at the head of intellectual society; and had become as distinguished by his conversational as his literary powers. He had become as much an autocrat in his sphere as his fellow-wayfarer and adventurer Garrick had become of the stage, and had been humorously dubbed by Smollett "The Great Cham of Literature."

Such was Dr. Johnson, when, on the 31st of May, 1761, he was to make his appearance as a guest at a literary supper given by Goldsmith, to a numerous party at his new lodgings in Wine-office-court. It was the opening of their acquaintance. Johnson had felt and acknowledged the merit of Goldsmith as an author, and been pleased by the honourable mention made of himself in the "Bee" and the "Chinese Letters." Dr. Percy called upon Johnson to take him to Goldsmith's lodgings; he found Johnson arrayed with unusual care in a new suit of clothes, a new hat, and a well-powdered wig; and could not but notice his uncommon spruceness. "Why, sir," replied Johnson, "I hear that Goldsmith, who is a very great sloven, justifies his disregard of cleanliness and decency by quoting my practice, and I am desirous this night to show him a better example."

The acquaintance thus commenced ripened into intimacy in the course of frequent meetings at the shop of Davies, the bookseller, in Russell-street, Covent-Garden. As this was one of the great literary gossiping places of the day, especially to the circle over which Johnson presided, it is worthy of some specification. Mr. Thomas Davies, noted in after times as the biographer of Garrick, had originally been on the stage, and though a small man, had enacted tyrannical tragedy with a pomp and magniloquence beyond his size, if we may trust the description given of him by Churchill in the "Rosciad":—

Statesman all over—in plots famous grown,  
He mouths a sentence as curs mouth a bone.

This unlucky sentence is said to have crippled him in the midst of his tragic career, and ultimately to have driven him from the stage. He carried into the book-selling craft somewhat of the grandiose manner of the stage, and was prone to be mouthy and magniloquent.

Churchill had intimated, that while on the stage he was more noted for his pretty wife than his good acting:—

With him came mighty Davies; on my life  
That fellow has a very pretty wife.

"Pretty Mrs. Davies" continued to be the lode-star of his fortunes. Her tea-table became almost as much a literary lounge as her husband's shop. She found favour in the eyes of the Urbs Major of literature by her winning ways, and she poured out for him cups without stint of his favourite beverage. Indeed, it is suggested that she was one leading cause of his habitual resort to this literary haunt. Others were drawn thither for the sake of Johnson's conversation, and thus it became the resort of many of the notorieties of the day. Here might occasionally be seen Bennet Langton, George Stephens, Dr. Percy, celebrated for his ancient ballads, and sometimes Warburton, in prelate's state. Garrick resorted to it for a time, but soon grew shy and suspicious, declaring that most of the authors who frequented Mr. Davies's shop went merely to abuse him.

Foote, the Aristophanes of the day, was a frequent visitor; his broad face beaming with fun and waggy, and his satirical eye ever on the look-out for characters and incidents for his farces. He was struck with the old habits and appearances of Johnson and Goldsmith, now so often brought together in Davies's shop. He was about to put on the stage a farce called "The Orators," intended as a hit at the Robin Hood debating club, and resolved to show up the two doctors in it for the entertainment of the town.

"What is the common price of an oak stick, sir," said Johnson to Davies. "Sixpence," was the reply. "Why, then, sir, give me leave to send your servant to purchase a shilling one. I'll have a double quantity; for I am told Foote means to take me off, as he calls it, and I am determined he shall not do it with impunity."

Foote had no wish to undergo the criticism of the cudgel, wielded by two such potent hands, so the farce of "The Orators" appeared without the caricatures of the lexicographer and the essayist.

### CHAP. XIII.

Oriental projects—Literary jobs—The Cherokee Chiefs—Merry Islington and the White Conduit House—Letters on the History of England—James Boswell—Dinner of Davies—Anecdotes of Johnson and Goldsmith.

Notwithstanding his growing success, Goldsmith continued to consider literature as a mere make-shift, and his vagrant imagination teemed with schemes and plans of a grand but indefinite nature. One was for visiting the East and exploring the interior of Asia. He had, as has been before observed, a vague notion that valuable discoveries were to be made there, and many useful inventions in the arts brought back to the stock of European knowledge. "Thus, in Siberian Tartary," observes he, in one of his writings, "the natives extract a strong spirit from milk, which is a secret probably unknown to the chemists of Europe. In the most savage parts of India they are possessed of the secret of dyeing vegetable substances scarlet, and that of refining lead into a metal which, for hardness and colour, is little inferior to silver."

Goldsmith adds a description of the kind of person suited to such an enterprise, in which he evidently had himself in view.

"He should be a man of a philosophical turn, one apt to deduce consequences of general utility from particular occurrences; neither swollen with pride nor hardened with prejudice; neither wedded to one particular system, nor instructed only in one particular science; neither wholly a botanist, nor quite an antiquarian; his mind should be tintured with miscellaneous knowledge, and his manners humanized by an intercourse with men. He should be in some measure an enthusiast to the design; fond of travelling from a rapid imagination and innate love of change; furnished

with a body capable of sustaining every fatigue, and a heart not easily terrified at danger.

In 1761, when Lord Bute became prime minister on the accession of George the Third, Goldsmith drew up a memorial on the subject, suggesting the advantages to be derived from a mission to those countries solely for useful and scientific purposes; and, the better to ensure success, he preceded his application to the government by an ingenious essay to the same effect in the "Public Ledger."

His memorial and his essay were fruitless, his project most probably being deemed the dream of a visionary. Still it continued to haunt his mind, and he would often talk of making an expedition to Aleppo some time or other, when his means were greater, to inquire into the arts peculiar to the East, and to bring home such as might be valuable. Johnson, who knew how little poor Goldsmith was fitted by scientific lore for this favourite scheme of his fancy, scoffed at the project when it was mentioned to him. "Of all men," said he, "Goldsmith is the most unfit to go out upon such an inquiry, for he is utterly ignorant of such arts as we already possess, and, consequently, could not know what would be accessions to our present stock of mechanical knowledge. Sir, he would bring home a grinding barrow, which you see in every street in London, and think that he had furnished a wonderful improvement."

His connexion with Newbery, the bookseller, now led him into a variety of temporary jobs, such as a pamphlet on the Cock-lane Ghost, a "Life of Beau Nash," the famous master of ceremonies at Bath, &c. One of the best things for his fame, however, was the remodelling and republication of his "Chinese Letters," under the title of "The Citizen of the World," a work which has long since taken its merited stand among the classics of the English language. "Few works," it has been observed by one of his biographers, "exhibit a nicer perception or more delicate delineation of life and manners. Wit, humour, and sentiment pervade every page; the vices and follies of the day are touched with the most playful and diverting satire; and English characteristics, in endless variety, are hit off with the pencil of a master."

In seeking materials for his varied views of life, he often mingled in strange scenes and got involved in whimsical situations. In the summer of 1762, he was one of the thousands who went to see the Cherokee chiefs, whom he mentions in one of his writings. The Indians made their appearance in grand costumes, hideously painted and besmeared. In the course of the visit Goldsmith made one of the chiefs a present, who, in the ecstasy of his gratitude, gave him an embrace, that left his face well bedaubed with oil and red ochre.

Towards the close of 1762 he removed to "merry Islington," then a country village, though now swallowed up in omnivorous London. He went there for the benefit of country air, his health being injured by literary application and confinement, and to be near his chief employer, Mr. Newbery, who resided in the Canonbury House. In this neighbourhood he used to take his solitary rambles, sometimes extending his walks to the gardens of the "White Conduit House," so famous among the essayists of the last century. While strolling one day in these gardens, he met three females of the family of a respectable tradesman, to whom he was under some obligation. With his prompt disposition to oblige he conducted them about the garden, treated them to tea, and ran up a bill in the most open-handed manner imaginable; it was only when he came to pay that he found himself in one of his old dilemmas—he had not the wherewithal in his pocket. A scene of perplexity now took place between him and the waiter, in the midst of which came up some of his acquaintances, in whose eyes he wished to stand particularly well. This completed his mortification. There was no concealing the awkwardness of his position—the sneers of the waiter

revealed it. His acquaintances amused themselves for some time at his expense, professing their inability to relieve him. When, however, they had enjoyed their banter, the waiter was paid, and poor Goldsmith enabled to convoy off the ladies with flying colours.

Among the various productions thrown off by him for the booksellers during this growing period of his reputation, was a small work in two volumes, entitled "The History of England, in a series of Letters from a Nobleman to his Son." It was digested from Hume, Rapin, Carte, and Kennet. These authors he would read in the morning; make a few notes; ramble with a friend into the country about the skirts of "merry Islington;" return to a temporary dinner and cheerful evening; and before going to bed, write off what had arranged itself in his head from the studies of the morning. In this way he took a more general view of the subject, and wrote in a more free and fluent style than if he had been mousing at the time among authorities. The work, like many others written by him in the earlier part of his literary career, was anonymous. Some attributed it to Lord Chesterfield, others to Lord Orrery, and others to Lord Lyttleton. The latter seemed to be pleased to be the putative father, and never disowned the bantering thus laid at his door; and well might he have been proud to be considered capable of producing what has been well-pronounced "the most finished and elegant summary of English history in the same compass that has been or is likely to be written."

The reputation of Goldsmith, it will be perceived, grew slowly; he was known and estimated by a few; but he had not those brilliant though fallacious qualities which flash upon the public, and excite loud but transient applause. His works were more read than cited; and the charm of style, for which he was especially noted, was more apt to be felt than talked about. He used often to repine, in a half-humorous, half-querulous manner, at his tardiness in gaining the laurels which he felt to be his due. "The public," he would exclaim, "will never do me justice; whenever I write anything, they make a point to know nothing about me."

About the beginning of 1763 he became acquainted with Boswell, whose literary gossipings were destined to have a deleterious effect upon his reputation. Boswell was at that time a young man, light, buoyant, pushing, and presumptuous. He had a morbid passion for mingling in the society of men noted for wit and learning, and had just arrived from Scotland, bent upon making his way into the literary circles of the metropolis. An intimacy with Dr. Johnson, the great literary luminary of the day, was the crowning object of his aspiring and somewhat ludicrous ambition. He expected to meet him at a dinner to which he was invited at Davie's, the bookseller's, but was disappointed. Goldsmith was present, but he was not as yet sufficiently renowned to excite the reverence of Boswell. "At this time," says he in his notes, "I think he had published nothing with his name, though it was pretty generally understood that one Dr. Goldsmith was the author of 'An Inquiry into the Present State of Polite Learning in Europe,' and of 'The Citizen of the World,' a series of letters supposed to be written from London by a Chinese."

A conversation took place at a table between Goldsmith and Mr. Robert Dodsley, compiler of the well-known collection of modern poetry, as to the merits of the current poetry of the day. Goldsmith declared there was none of superior merit. Dodsley cited his own collection in proof of the contrary. "It is true," said he, "we can boast of no palaces now-a-days, like 'Dryden's Ode to St. Cecilia's Day,' but we have villages composed of very pretty houses." Goldsmith, however, maintained that there was nothing above mediocrity, an opinion in which Johnson, to whom it was repeated, concurred, and with reason, for the era was one of the dead levels of British poetry.

Boswell has made no note of this conversation; he was an unitarian in his literary devotion, and disposed to worship none but Johnson. Little Davies endeavoured to console him for his disappointment, and to stay the stomach of his curiosity, by giving him imitations of the great lexicographer; mouthing his words, rolling his head, and assuming as ponderous a manner as his petty person would permit. Boswell was shortly afterwards made happy by an introduction to Johnson, of whom he became the obsequious satellite. From him he likewise imbibed a more favourable opinion of Goldsmith's merits, though he was fain to consider them derived in a great measure from his Magnus Apollo. "He had sagacity enough," says he, "to cultivate assiduously the acquaintance of Johnson, and his faculties were gradually enlarged by the contemplation of such a model. To me and many others it appeared that he studiously copied the manner of Johnson, though, indeed, upon a smaller scale." So, on another occasion, he calls him "one of the brightest ornaments of the Johnsonian school." "His respectful attachment to Johnson," adds he, "was then at its height; for his own literary reputation had not yet distinguished him so much as to excite a desire of competition with his great master." "What beautiful instances does the garrulous Boswell give of the goodness of heart of Johnson, and the passing homage to it by Goldsmith. They were speaking of a Mr. Levett, long an inmate of Johnson's house and a dependent on his bounty; and who, Boswell thought, must be an irksome charge upon him. "He is poor and honest," said Goldsmith, "which is recommendation enough to Johnson."

Boswell mentioned another person of a very bad character, and wondered at Johnson's kindness to him. "He is now become miserable," said Goldsmith, "and that insures the protection of Johnson." Encomiums like these speak almost as much for the heart of him who praises as of him who is praised.

Subsequently, when Boswell had become more intense in his literary idolatry, he affected to undervalue Goldsmith, and a lurking hostility to him is discernible throughout his writings, which some have attributed to a silly spirit of jealousy of the superior esteem evinced for the poet by Dr. Johnson. We have a gleam of this in his account of the first evening he spent in company with those two eminent authors at their famous resort, the Mitre Tavern, in Fleet-street. This took place on the 1st of July, 1768. The trio supped together, and passed some time in literary conversation. On quitting the tavern, Johnson, who had now been sociably acquainted with Goldsmith for two years, and saw his merits, took him with him to drink tea with his blind pensioner, Miss Williams—a high privilege among his intimates and admirers. To Boswell, a recent acquaintance, whose intrusive sycophancy had not yet made its way into his confidential intimacy, he gave no invitation. Boswell felt it with all the jealousy of a little mind. "Dr. Goldsmith," says he, in his memoirs, "being a privileged man, went with him, strutting away, and calling to me with an air of superiority, like that of an estroper over an exoteric disciple of a sage of antiquity. 'I go to Miss Williams.' I confess I then envied him this mighty privilege, of which he seemed to be so proud; but it was not long before I obtained the same mark of distinction."

Obtained! but how? not like Goldsmith, by the force of unpretending but congenial merit, but by a course of the most pushing, contriving, and spaniel-like subserviency. Really, the ambition of the man to illustrate his mental insignificance, by continually placing himself in juxtaposition with the great lexicographer, has something in it perfectly ludicrous. Never, since the days of Don Quixote and Sancho Panza has there been presented to the world a more whimsically contrasted pair of associates than Johnson and Boswell.

"Who is this Scotch cur at Johnson's heels?" asked some one, when Boswell had worked his way into incessant companionship. "He is not a cur," replied Goldsmith, "you are too severe; he is only a burr. Tom Davies flung him at Johnson in sport, and he has the faculty of sticking."

#### CHAP. XIV.

Hogarth a visitor at Islington—His character—Street studies—Sympathies between authors and painters—Sir Joshua Reynolds—His character—His dinners—The Literary Club—Its members—Johnson's revels with Lanky and Beau—Goldsmith at the club.

Among the intimates who used to visit the poet occasionally in his retreat at Islington was Hogarth the painter. Goldsmith had spoken well of him in his essays in the "Public Ledger," and this formed the first link in their friendship. He was at this time upwards of sixty years of age, and is described as a stout, active, bustling little man, in a sky-blue coat, satirical and dogmatic, yet full of real benevolence and the love of human nature. He was the moralist and philosopher of the pencil; like Goldsmith, he had sounded the depths of vice and misery without being polluted by them; and though his picturings had not the pervading amenity of those of the essayist, and dwelt more on the crimes and vices than the follies and humours of mankind, yet they were all calculated in like manner to fill the mind with instruction and precept, and to make the heart better.

Hogarth does not appear to have had much of the rural feeling with which Goldsmith was so amply endowed, and may not have accompanied him in his strolls about hedges and green lanes; but he was a fit companion with whom to explore the mazes of London, in which he was continually on the look out for character and incident. One of Hogarth's admirers speaks of having come upon him in Castle-street, engaged in one of his street studies—watching two boys who were quarrelling, patting one on the back who flinched, and endeavouring to spirit him up to a fresh encounter. "At him again! D—him, if I would take it of him! at him again!"

A frail memorial of this intimacy between the painter and the poet exists in a portrait in oil, called "Goldsmith's Hostess." It is supposed to have been painted by Hogarth in the course of his visits to Islington, and given by him to the poet as a means of paying his landlady. There are no friendships among men of talents more likely to be sincere than those between painters and poets. Possessed of the same qualities of mind, governed by the same principles of taste and natural laws of grace and beauty, but applying them to different yet mutually illustrative arts, they are constantly in sympathy, and never in collision with each other.

A still more congenial intimacy of the kind was that contracted by Goldsmith with Mr. (afterwards Sir Joshua) Reynolds. The latter was now about forty years of age, a few years older than the poet, whom he charmed by the blandness and benignity of his manners, and the nobleness and generosity of his disposition; as much as he did by the graces of his pencil and the magic of his colouring. They were men of kindred genius, excelling in corresponding qualities of their several arts—for style in writing is what colour is in painting; both are innate endowments, and equally magical in their effects. Certain graces and harmonies of both may be acquired by diligent study and imitation, but only in a limited degree; whereas by their natural possessors they are exercised spontaneously and unconsciously, and with ever-varying fascination. Reynolds soon understood and appreciated the merits of Goldsmith, and a sincere and lasting friendship ensued between them.

At Reynolds's house Goldsmith mingled in a higher range of company than he had been accustomed to. The fame of this celebrated artist, and his amenity of manners, were gathering round him men of talents of all kinds, and the increasing affluence of his circumstances enabled him to give full indulgence to his hospitable disposition. Poor Goldsmith had not yet, like Dr. Johnson, acquired reputation enough to atone for his external defects and his want of the air of good society. Miss Reynolds used to inveigh against his personal appearance, which gave her the idea, she said, of a low mechanic, a journeyman tailor. One evening, at a large supper party, being called upon to give as a toast the ugliest man she knew, she gave Dr. Goldsmith, upon which a lady who sat opposite, and whom she had never met before, shook hands with her across the table, and "hoped to become better acquainted."

We have a graphic and amusing picture of Reynolds's hospitable but motley establishment, in an account given by a Mr. Courtenay to Sir James Mackintosh; though it speaks of a time after Reynolds had received the honour of knighthood. "There was something singular," said he, "in the style and economy of Sir Joshua's table that contributed to pleasantness and good humour—a coarse, inelegant plenty, without any regard to order and arrangement. At five o'clock precisely dinner was served, whether all the invited guests were arrived or not. Sir Joshua was never so fashionably ill-bred as to wait an hour, perhaps, for two or three persons of rank or title, and put the rest of the company out of humour by this invidious distinction. His invitations, however, did not regulate the number of his guests. Many dropped in uninvited. A table prepared for seven or eight was often compelled to contain fifteen or sixteen. There was a consequent deficiency of knives, forks, plates, and glasses. The attendance was in the same style, and those who were knowing in the ways of the house took care, on sitting down, to call instantly for beer, bread, or wine, that they might secure a supply before the first course was over. He was once prevailed on to furnish the table with decanters and glasses at dinner, to save time and prevent confusion. These gradually were demolished in the course of service, and were never replaced. These trifling embarrassments, however, only served to enhance the hilarity and singular pleasure of the entertainment. The wine, cookery, and dishes were but little attended to; nor was the fish or venison ever talked of or recommended. Amidst this convivial animated bustle among his guests our host sat perfectly composed; always attentive to what was said, never minding what was ate or drank, but left every one at perfect liberty to scramble for himself."

Out of the casual but frequent meeting of men of talent at this hospitable board rose that association of wits, authors, scholars, and statesmen, renowned as the Literary Club. Reynolds was the first to propose a regular association of the kind, and was eagerly seconded by Johnson, who proposed as a model a club which he had formed many years previously in Ivy-lane, but which was now extinct. Like that club the number of members was limited to nine. They were to meet and sup together once a week, on Monday night, at the Turk's Head in Gerard-street, Soho, and two members were to constitute a meeting. It took a regular form in the year 1764, but did not receive its literary appellation until several years afterwards.

The original members were Reynolds, Johnson, Burke, Dr. Nugent, Bennet Langton, Topham Beauclerc, Chamier, Hawkins, and Goldsmith; and here a few words concerning some of the members may be acceptable. Burke was at that time about thirty-three years of age; he had mingled a little in politics, and been under-secretary to Hamilton at Dublin, but was again a writer for the booksellers, and as yet but in the dawning of his fame. Dr. Nugent was his father-in-

law, a Roman Catholic, and a physician of talent and instruction. Mr. (afterwards Sir John) Hawkins was admitted into this association from having been a member of Johnson's Ivy-lane club. Originally an attorney, he had retired from the practice of the law, in consequence of a large fortune which fell to him in the right of his wife, and was now a Maitland magistrate. He was, moreover, a dabbler in literature and music, and was actually engaged on a history of music, which he subsequently published in five ponderous volumes. To him we are also indebted for a biography of Johnson, which appeared after the death of that eminent man. Hawkins was as mean and parsimonious as he was pompous and conceited. He forbore to partake of the suppers at the club, and begged, therefore, to be excused from paying his share of the reckoning. "And was he excused?" asked Dr. Burney of Johnson. "Oh yes, for no man is angry at another for being inferior to himself. We all scorned him and admitted his plea. Yet I really believe him to be an honest man at the bottom, though to be sure he is penurious, and he is mean, and it must be owned he has a tendency to savageness." He did not remain above two or three years in the club; being in a manner elbowed out in consequence of his rudeness to Burke.

Mr. Anthony Chamier was secretary in the war-office, and a friend of Beauclerc, by whom he was proposed. We have left our mention of Bennet Langton and Topham Beauclerc until the last, because we have most to say about them. They were doubtless induced to join the club through their devotion to Johnson, and the intimacy of these two very young and aristocratic young men with the stern and somewhat melancholy moralist is among the curiosities of literature.

Bennet Langton was of an ancient family, who held their ancestral estate of Langton in Lincolnshire—a great title to respect with Johnson. "Langton, sir," he would say, "has a grant of free warren from Henry the Second; and Cardinal Stephen Langton, in King John's reign, was of this family."

Langton was of a mild, contemplative, enthusiastic nature. When but eighteen years of age, he was so delighted with reading Johnson's "Rambler," that he came to London chiefly with a view to obtain an introduction to the author. Boswell gives us an account of his first interview, which took place in the morning. It is not often that the personal appearance of an author agrees with the preconceived ideas of his admirer. Langton, from perusing the writings of Johnson, expected to find him a decent, well-dressed—in short a remarkably decorous philosopher. Instead of which, down from his bedchamber, about noon, came, as newly risen, a large uncouth figure, with a little dark wig which scarcely covered his head, and his clothes hanging loose about him. But his conversation was so rich, so animated, and so forcible, and his religious and political notions so congenial with those in which Langton had been educated, that he conceived for him that veneration and attachment which he ever preserved.

Langton went to pursue his studies at Trinity College, Oxford, where Johnson saw much of him during a visit which he paid to the university. He found him in close intimacy with Topham Beauclerc, a youth two years older than himself, very gay and dissipated, and wondered what sympathies could draw two young men together of such opposite characters. On becoming acquainted with Beauclerc, he found that, rake though he was, he possessed an ardent love of literature, an acute understanding, polished wit, innate gentility, and high aristocratic breeding. He was, moreover, the only son of Lord Sidney Beauclerc, and grandson of the Duke of St. Albans, and was thought in some particulars to have a resemblance to Charles the Second. These were high recommendations with Johnson; and when the youth testified a profound respect for him,

and an ardent admiration of his talents, the conquest was complete, so that in a "short time," says Boswell, "the moral, pious Johnson and the gay, dissipated Beauclerc were companions."

The intimacy begun in college chambers was pleasantly continued when the youths came to town during the vacations. The uncouth, unwieldy moralist was flattered at finding himself an object of idolatry to two high-born, high-bred young men, and, throwing gravity aside, was ready to join in their vagaries and play the part of a "young man upon town." Such at least is the picture given of him by Boswell on one occasion, when Beauclerc and Langton, having supped together at a tavern, determined to give Johnson a rouse at three o'clock in the morning. They accordingly rapped violently at the door of his chambers in the Temple. The indignant sage sallied forth in his shirt, poker in hand, and a little black wig on the top of his head instead of helmet, prepared to wreak vengeance on the assailants of his castle; but when his two young friends, *Lankey* and *Beau*, as he used to call them, presented themselves, summoning him forth to a morning ramble, his whole manner changed. "What, is it you, ye dogs?" cried he; "faith I'll have a frisk with you!"

So said, so done. They sallied forth together into Covent Garden; figured among the green-grocers and fruit-women, just come in from the country with their hampers; repaired to a neighbouring tavern, where Johnson brewed a bowl of *bishop* (a favourite beverage with him), grew merry over his cups, and anathematised sleep in two lines from Lord Lansdowne's drinking song:—

Short, very short, be then thy reign,  
For I'm in haste to laugh and drink again.

They then took boat again, rowed to Billingsgate, and Johnson and Beauclerc determined, like "mad wags," to "keep it up" for the rest of the day. Langton, however, the most sober-minded of the three, pleaded an engagement to breakfast with some young ladies; whereupon the great moralist reproached him with "leaving his social friends to go and sit with a set of wretched *un-ideal* girls."

This madcap freak of the great lexicographer made a sensation, as may well be supposed, among his intimates. "I heard of your frolic to'other night," said Garrick to him; "you'll be in the 'Chronicle.'" He uttered worse forebodings to others. "I shall have my old friend to bail out of the roundhouse," said he. Johnson, however, valued himself upon having thus enacted a chapter in the "Rake's Progress," and crowded over Garrick on the occasion. "He durst not do such a thing!" chuckled he; "his wife would not let him!"

When these two young men entered the club, Langton was about twenty-two, and Beauclerc about twenty-four years of age, and both were launched on London life. Langton, however, was still the mild, enthusiastic scholar, steeped to the lips in Greek, with fine conversational powers, and an invaluable talent for listening. He was upwards of six feet high, and very spare. "Oh! that we could sketch him," exclaimed Miss Hawkins, in her *Memoirs*, "with his mild countenance, his elegant features, and his sweet smile, sitting with one leg twisted round the other, as if fearing to occupy more space than was equitable; his person inclining forward, as if wanting strength to support his weight, and his arms crossed over his bosom, or his hands locked together on his knee." Beauclerc, on such occasions, sportively compared him to a stork in Raphael's Cartoons, standing on one leg. Beauclerc was more a "man upon town," a loungeur in St. James's-street, an associate with George Selwyn, with Walpole, and other aristocratic wits; a man of fashion at court; a casual frequenter of the gaming-table; yet, with all this, he alternated in the easiest and happiest manner the scholar and the man of letters; lounged into the club with the most perfect

self-possession, bringing with him the careless grace and polished wit of high-bred society, but making himself cordially at home among his learned fellow-members.

The gay lettered rake maintained his sway over Johnson, who was fascinated by that air of the world, that ineffable tone of good society in which he felt himself deficient, especially as the possessor of it always paid homage to his superior talent. "Beauclerc," he would say, using a quotation from Pope, "has a love of folly, but a scorn of fools; everything he does shows the one, and everything he says the other." Beauclerc delighted in rallying the stern moralist, of whom others stood in awe, and no one, according to Boswell, could take equal liberty with him with impunity. Johnson, it is well known, was often shabby and negligent in his dress, and not over-cleanly in his person. On receiving a pension from the crown, his friends vied with each other in respectful congratulations. Beauclerc simply scanned his person with a whimsical glance, and hoped that, like Falstaff, "he'd in future purge and live cleanly like a gentleman." Johnson took the hint with unexpected good humour, and profited by it.

Still Beauclerc's satirical vein, which darted shafts on every side, was not always tolerated by Johnson. "Sir," said he, on one occasion, "you never open your mouth but with intention to give pain; and you have often given me pain, not from the power of what you have said, but from seeing your intention."

When it was at first proposed to enrol Goldsmith among the members of this association, there seems to have been some demur; at least so says the pompous Hawkins. "As he wrote for the booksellers, we of the club looked on him as a mere literary drudge, equal to the task of compiling and translating, but little capable of original, and still less of poetical composition."

Even for some time after his admission, he continued to be regarded in a dubious light by some of the members. Johnson and Reynolds, of course, were well aware of his merits, nor was Burke a stranger to them; but to the others he was as yet a sealed book, and the outside was not prepossessing. His ungainly person and awkward manners were against him with men accustomed to the graces of society, and he was not sufficiently at home to give play to his humour, and to that *bonhomie* which won the hearts of all who knew him. He felt strange and out of place in this sphere; he felt at times the cool satirical eye of the courtly Beauclerc scanning him, and the more he attempted to appear at his ease the more awkward he became.

## CHAP. XV.

Johnson a monitor to Goldsmith—Finds him in distress with his landlady—Relieved by the "Vicar of Wakefield"—The oratorio—Poem of "The Traveller"—The poet and his dog—Success of the poem—Astonishment of the club—Observations on the poem.

Johnson had now become one of Goldsmith's best friends and advisers. He knew all the weak points of his character, but he knew also his merits; and while he would rebuke him like a child, and rail at his errors and follies, he would suffer no one else to undervalue him. Goldsmith knew the soundness of his judgment and his practical benevolence, and often sought his counsel and aid amid the difficulties into which his heedlessness was continually plunging him.

"I received one morning," says Johnson, "a message from poor Goldsmith that he was in great distress, and, as it was not in his power to come to me, begging that I would come to him as soon as possible. I sent him a guinea, and promised to come to him directly. I accordingly went as soon as I was dressed, and found that his landlady had arrested him for his rent, at which he was

in a violent passion: I perceived that he had already changed my guinea, and had a bottle of Madeira and a glass before him. I put the cork into the bottle, desired he would be calm, and began to talk to him of the means by which he might be extricated. He then told me he had a novel ready for the press, which he produced to me. I looked into it, and saw its merit; told the landlady I should soon return; and, having gone to a bookseller, sold it for sixty pounds. I brought Goldsmith the money, and he discharged his rent, not without rating his landlady in a high tone for having used him so ill."

The novel in question was the "Vicar of Wakefield;" the bookseller to whom Johnson sold it was Francis Newbery, nephew to John. Strange as it may seem, this captivating work, which has obtained and preserved an almost unrivalled popularity in various languages, was so little appreciated by the bookseller, that he kept it by him nearly two years unpublished!

Goldsmith had as yet produced nothing of moment in poetry. Among his literary jobs, it is true, was an oratorio entitled "The Captivity," founded on the bondage of the Israelites in Babylon. It was one of those unhappy offsprings of the muse ushered into existence amid the distortions of music. Most of the oratorio has passed into oblivion; but the following song from it will never die:—

The wretch condemn'd from life to part,  
Still, still on hope relies,  
And ev'ry pang that rends the heart  
Bids expectation rise.

Hope, like the glimmering taper's light,  
Illumes and cheers our way;  
And still, as darker grows the night,  
Emits a brighter ray.

Goldsmith distrusted his qualifications to succeed in poetry, and doubted the disposition of the public mind in regard to it. "I fear," said he, "I have come too late into the world; Pope and other poets have taken up the places in the Temple of fame; and as few at any period can possess poetical reputation, a man of genius can now hardly acquire it." Again, on another occasion he observes—"Of all kinds of ambition, as things are now circumstanced, perhaps that which pursues poetical fame is the wildest. What from the increased refinement of the times, from the diversity of judgment produced by opposing systems of criticism, and from the more prevalent divisions of opinion influenced by party, the strongest and happiest efforts can expect to please but in a very narrow circle."

At this very time he had by him his poem of "The Traveller." The plan of it, as has already been observed, was conceived many years before, during his travels in Switzerland, and a sketch of it sent from that country to his brother Henry in Ireland. The original outline is said to have embraced a wider scope; but it was probably contracted through diffidence in the process of finishing the parts. It had laid by him for several years in a crude state, and it was with extreme hesitation, and after much revision, that he at length submitted it to Dr. Johnson. The frank and warm approbation of the latter encouraged him to finish it for the press; and Dr. Johnson himself contributed a few lines towards the conclusion.

We hear much about "poet's inspiration," and the "poet's eye in a fine frenzy rolling;" but Sir Joshua Reynolds gives an anecdote of Goldsmith while engaged upon his poem, calculated to cure our notions about the ardour of composition. Calling upon the poet one day, he opened the door without ceremony, and found him in the double occupation of turning a couplet and teaching a pet dog to sit upon his haunches. At one time he would glance his eye at his desk, and at another shake his finger at the dog to make him retain his position.

The last lines on the page were still wet; they form a part of the description of Italy—

By sports like these are all their cares beguiled—  
The sports of children satisfy the child.

Goldsmith, with his usual good humour, joined in the laugh caused by his whimsical employment, and acknowledged that his boyish sport with the dog suggested the stanza.

The poem was published on the 19th of December, 1764, in a quarto form, by Newbery, and was the first of his works to which Goldsmith prefixed his name. As a testimony of cherished and well-merited affection, he dedicated it to his brother Henry. There is an amusing affectation of indifference as to its fate expressed in the dedication. "What reception a poem may find," says he, "which has neither abuse, party, nor blank verse to support it, I cannot tell, nor am I solicitous to know." The truth is, no one was more emulous and anxious for poetic fame; and never was he more anxious than in the present instance, for it was his grand stake. Dr. Johnson aided the launching of the poem by a favourable notice in the "Critical Review;" other periodical works came out in its favour. Some of the author's friends complained that it did not command instant and wide popularity—that it was a poem to win, not to strike. It went on rapidly increasing in favour; in three months a second edition was issued: shortly afterwards, a third; then a fourth; and, before the year was out, the author was pronounced the best poet of his time.

The appearance of "The Traveller" at once altered Goldsmith's intellectual standing in the estimation of society; but its effect upon the club, if we may judge from the account given by Hawkins, was most ludicrous. They were lost in astonishment that a "newspaper essayist" and "bookseller's drudge" should have written such a poem. On the evening of its announcement to them, Goldsmith had gone away early, after rattling away as usual, and they knew not how to reconcile his heedless garrulity with the serene beauty, the easy grace, the sound good sense, and the occasional elevation of his poetry. They could scarcely believe that such magic numbers had flowed from a man to whom in general, says Johnson, "it was with difficulty they could give a hearing." "Well," exclaimed Chamier, "I do believe he wrote this poem himself; and let me tell you, that is believing a great deal."

At the next meeting of the club Chamier sounded the author a little about his poem. "Mr. Goldsmith," said he, "what do you mean by the last word in the first line of your Traveller, 'remote, unfriended, solitary, *slow*?' do you mean tardiness of locomotion?"—"Yes," replied Goldsmith, inconsiderately, being probably flurried at the moment. "No, sir," interposed his protesting friend Johnson, "you did not mean tardiness of locomotion; you meant that sluggishness of mind which comes upon a man in solitude."—"Ah!" exclaimed Goldsmith, "that was what I meant." Chamier immediately believed that Johnson himself had written the line, and a rumour became prevalent that he was the author of many of the finest passages. This was ultimately set at rest by Johnson himself, who marked with a pencil all the verses he had contributed, nine in number inserted towards the conclusion, and by no means the best in the poem. He moreover, with generous warmth, pronounced it the finest poem that had appeared since the days of Pope.

But one of the highest testimonials to the charm of the poem was given by Miss Reynolds, who had toasted poor Goldsmith as the ugliest man of her acquaintance. Shortly after the appearance of "The Traveller," Dr. Johnson read it aloud from beginning to end in her presence. "Well," exclaimed she, when he had finished, "I never more shall think Dr. Goldsmith ugly!"

On another occasion, when the merits of "The Traveller" were discussed at Reynolds's board, Langton declared "there was not a bad line in the poem, not one of Dryden's careless verses." "I was glad," observed Reynolds, "to hear Charles Fox say it was one of the finest poems in the English language." "Why was you glad?" rejoined Langton, "you surely had no doubt of this before." "No," interposed Johnson, decisively; "the merit of 'The Traveller' is so well established, that Mr. Fox's praise cannot augment it, nor his censure diminish it."

Boswell, who was absent from England at the time of the publication of "The Traveller," was astonished, on his return, to find Goldsmith, whom he had so much undervalued, suddenly elevated almost to a par with his idol. He accounted for it by concluding, that much both of the sentiments and expression of the poem had been derived from conversations with Johnson. "He imitates you, sir," said this incarnation of toadyism. "Why, no, sir," replied Johnson, "Jack Hawkesworth is one of my imitators, but not Goldsmith. Goldy, sir, has great merit." "But, sir, he is much indebted to you for his getting so high in the public estimation." "Why, sir, he has, perhaps, got sooner to it by his intimacy with me."

The poem went through several editions in the course of the first year, and received some few additions and corrections from the author's pen. It produced a golden harvest to Mr. Newbery, but all the remuneration on record doled out by his niggard hand to the author was twenty guineas!

#### CHAP. XVI.

New lodgings—Johnson's compliment—A titled patron—The poet at Northumberland House—His independence of the great—The Countess of Northumberland—"Edwin and Angelina"—Gosford and Lord Clare—Publication of his "Essays"—Evils of a rising reputation—Hangers-on—Job writing—Goody Two-Shoes—A medical campaign—Mrs. Sidebotham.

Goldsmith, now that he was rising in the world, and becoming a notoriety, felt himself called upon to improve his style of living. Accordingly he emerged from Wine office-court, and took chambers in the Temple. It is true they were but of humble pretensions, situated on what was then the library staircase, and it would appear that he was a kind of inmate with Jeffs, the butler of the society. Still he was in the Temple, that classic region rendered famous by the Spectator and other essayists as the abode of gay wits and thoughtful men of letters; and which, with its retired courts and embowered gardens, in the very heart of a noisy metropolis, is, to the quiet-seeking student and author, an oasis freshening with verdure in the midst of a desert. Johnson, who had become a kind of growling supervisor of the poet's affairs, paid him a visit soon after he had installed himself in his new quarters, and went prying about the apartment, in his near-sighted manner examining everything minutely. Goldsmith was fidgeted by this curious scrutiny, and apprehending a disposition to find fault, exclaimed, with the air of a man who had money in both pockets, "I shall soon be in better chambers than these." The harmless bravado drew a reply from Johnson, which touched the chord of proper pride. "Nay, sir," said he, "never mind that. *Nil te quæsieris extra.*" implying that his reputation rendered him independent of outward show. Happy would it have been for poor Goldsmith could he have kept this consolatory compliment perpetually in mind, and spared his expenses accordingly.

Among the persons of rank who were struck with the merits of "The Traveller" was the Earl (afterwards Duke)

of Northumberland. He procured several other of Goldsmith's writings, the perusal of which tended to elevate the author in his good opinion, and to gain for him his good will. The earl held the office of Lord-Lieutenant of Ireland, and understanding Goldsmith was an Irishman, was disposed to extend to him the patronage which his high post afforded. He intimated the same to his relative, Dr. Percy, who, he found, was well acquainted with the poet, and expressed a wish the latter should wait upon him. Here, then, was another opportunity for Goldsmith to better his fortune, had he been knowing and worldly enough to profit by it. Unluckily, the path to fortune lay through the aristocratical mazes of Northumberland House, and the poet blundered at the outset. The following is the account he used to give of his visit:—"I dressed myself in the best manner I could, and, after studying some compliments I thought necessary on such an occasion, proceeded to Northumberland House, and acquainted the servants that I had particular business with the duke. They showed me into an antechamber, where, after waiting some time, a gentleman, very elegantly dressed, made his appearance: taking him for the duke, I delivered all the fine things that I had composed in order to compliment him on the honour he had done me; when, to my great astonishment, he told me I had mistaken him for his master, who would see him immediately. At that instant the duke came into the apartment, and I was so confused on the occasion, that I wanted words barely sufficient to express the sense I entertained of the duke's politeness, and went away exceedingly chagrined at the blunder I had committed."

Sir John Hawkins, in his "Life of Dr. Johnson," gives some further particulars of this visit, of which he was, in part, a witness. "Having one day," says he, "a call to make on the late duke, then Earl, of Northumberland, I found Goldsmith waiting for an audience in an outer room: I asked him what had brought him there; he told me an invitation from his lordship. I made my business as short as I could, and, as a reason, mentioned that Dr. Goldsmith was waiting without. The earl asked me if I was acquainted with him. I told him that I was, adding what I thought was most likely to recommend him. I retired, and stayed in the outer room to take him home. Upon his coming out, I asked him the result of his conversation. 'His lordship,' said he, 'told me he had read my poem, meaning 'The Traveller,' and was much delighted with it; that he was going to be Lord-Lieutenant of Ireland, and that, bearing I was a native of that country, he should be glad to do me any kindness.' 'And what did you answer,' said I, 'to this gracious offer?' 'Why,' said he, 'I could say nothing but that I had a brother there, a clergyman, that stood in need of help: as for myself, I have no great dependence on the promises of great men; I look to the booksellers for support; they are my best friends, and I am not inclined to forsake them for others. Thus,' continues Sir John, 'did this idiot in the affairs of the world trifle with his fortune, and put back the hand that was held out to assist him.'"

We cannot join with Sir John in his worldly sneer at the conduct of Goldsmith on this occasion. While we admire that honest independence of spirit which prevented him from asking favours for himself, we love that warmth of affection which instantly sought to advance the fortunes of a brother; but the peculiar merits of poor Goldsmith seem to have been little understood by the Hawkinses, the Boswells, and the other biographers of the day.

After all, the introduction to Northumberland House did not prove so complete a failure as the humorous account given by Goldsmith, and the cynical account given by Sir John Hawkins, might lead one to suppose. Dr. Percy, the heir-male of the ancient Percies, brought the poet into the acquaintance of his kinswoman, the

countess, who, before her marriage with the earl, was in her own right heiress of the House of Northumberland. "She was a lady," says Boswell, "not only of high dignity of spirit, such as became her noble blood, but of excellent understanding and lively talents." Under her auspices, a poem of Goldsmith's had an aristocratic introduction to the world. This was the beautiful ballad of "The Hermit," originally published under the name of "Edwin and Angelina." It was suggested by an old English ballad beginning "Gentle Herdman," shown him by Dr Percy, who was at that time making his famous collection, entitled "Relics of Ancient English Poetry," which he submitted to the inspection of Goldsmith prior to publication. A few copies only of "The Hermit" were printed at first, with the following title-page:—"Edwin and Angelina: a Ballad. By Mr. Goldsmith. Printed for the Amusement of the Countess of Northumberland."

All this, though it may not have been attended with any immediate pecuniary advantage, contributed to give Goldsmith's name and poetry the high stamp of fashion so potent in England. The circle at Northumberland House, however, was of too steady and aristocratical a nature to be much to his taste, and we do not find that he became familiar in it.

He was much more at home at Gosford, the noble seat of his countryman, Viscount Clare, who appreciated his merits even more heartily than the Duke of Northumberland, and occasionally made him his guest both in town and country. Nugent is described as a jovial voluptuary, who left the Roman Catholic for the Protestant religion, with a view of bettering his fortunes: he had an Irishman's inclination for rich widows, and an Irishman's luck with the sex—having been thrice married, and gained a fortune with each wife. He was now nearly sixty, with a remarkably loud voice, broad Irish brogue, and ready but somewhat coarse wit. With all his occasional coarseness he was capable of high thought, and had produced poems which showed a truly poetic vein. He was long a member of the House of Commons, where his ready wit, his fearless decision, and good-humoured audacity of expression always gained him a hearing, though his tall person and awkward manner gave him the nickname of Squire Gawky among the political scribblers of the day. With a patron of this jovial temperament Goldsmith probably felt more at ease than with those of higher refinement.

The celebrity which Goldsmith had acquired by his poem of "The Traveller" occasioned a resuscitation of many of his miscellaneous and anonymous tales and essays from the various newspapers and transient publications in which they lay dormant. These he published in 1765 in a collected form, under the title of "Essays, by Mr. Goldsmith." "The following Essays," observes he in his preface, "have already appeared at different times and in different publications. The pamphlets in which they were inserted being generally unsuccessful, these shared the common fate, without assisting the booksellers' aims, or extending the author's reputation. The public were too strenuously employed with their own follies to be assiduous in estimating mine, so that many of my best attempts in this way have fallen victims to the transient topic of the times—the Ghost in Cock-lane, or the Siege of Ticonderoga."

"But, though they have passed pretty silently into the world, I can by no means complain of their circulation. The magazines and papers of the day have indeed been liberal enough in this respect. Most of these Essays have been regularly reprinted twice or thrice a year, and conveyed to the public through the kennel of some engaging compilation. If there be a pride in multiplied editions, I have seen some of my labours sixteen times reprinted, and claimed by different

parents as their own. I have seen them flourished at the beginning with praise, and signed at the end with the names of Philautos, Philalethes, Phileleutheros, and Philanthropos. It is time, however, at last to vindicate my claims; and as these entertainers of the public, as they call themselves, have partly lived upon me for some years, let me now try if I cannot live a little upon myself."

It was but little, in fact; for all the pecuniary emolument he received from the volume was twenty guineas. It had a good circulation, however, was translated into French, and has maintained its stand among the British classics.

Notwithstanding that the reputation of Goldsmith had greatly risen, his finances were often at a very low ebb, owing to his heedlessness as to expense, his liability to be imposed upon, and a spontaneous and irresistible propensity to give to every one who asked. The very rise in his reputation had increased these embarrassments. It had enlarged his circle of needy acquaintances—authors poorer in pocket than himself, who came in search of literary counsel; which generally meant a guinea and a breakfast. And then his Irish hangers-on! "Our Doctor," said one of these sponges, "had a constant levee of his distressed countrymen, whose wants, as far as he was able, he always relieved; and he has often been known to leave himself without a guinea in order to supply the necessities of others."

This constant drainage of the purse, therefore, obliged him to undertake all jobs proposed by the booksellers, and to keep a kind of running account with Mr. Newbery, who was his banker on all occasions, sometimes for pounds, sometimes for shillings; but who was a rigid accountant, and took care amply to be repaid in manuscript. Many effusions, hastily penned in these moments of exigency, were published anonymously, and never claimed. Some of them have but recently been traced to his pen; while of many the true authorship will probably never be discovered. Among others, it is suggested, and with great probability, that he wrote for Mr. Newbery the famous nursery story of "Goody Two-Shoes," which appeared in 1765, at a moment when Goldsmith was scribbling for Newbery, and much pressed for funds. Several quaint little tales introduced in his Essays show that he had a turn for this species of mock history; and the advertisement and title-page bear the stamp of his sly and playful humour:—

"We are desired to give notice, that there is in the press, and speedily will be published, either by subscription or otherwise, as the public shall please to determine, the History of Little Goody Two-Shoes, otherwise Mrs. Margery Two-Shoes; with the means by which she acquired learning and wisdom, and in consequence thereof, her estate; set forth at large for the benefit of those

Who, from a state of rags and care,  
And having shoes but half a pair,  
Their fortune and their fame should fix,  
And gallop in a coach-and-six."

The world is probably not aware of the ingenuity, humour, good sense, and sly satire contained in many of the old English nursery-tales. They have evidently been the sportive productions of able writers, who would not trust their names to productions that might be considered beneath their dignity. The ponderous works on which they relied for immortality have perhaps sunk into oblivion, and carried their names down with them; while their unacknowledged offspring, "Jack the Giant Killer," "Giles Gingerbread," and "Tom Thumb," flourish in wide-spreading and never-ceasing popularity.

As Goldsmith had now acquired popularity and an extensive acquaintance, he attempted, with the advice of his friends, to procure a more regular and ample support by resuming the medical profession. He accordingly launched himself upon the town in style; hired a

man-servant; replenished his wardrobe at considerable expense, and appeared in a professional wig and cane, purple silk small-clothes, and a scarlet roquelaure, buttoned to the chin; a fantastic garb, as we should think at the present day, but not unsuited to the fashion of the times.

With his sturdy little person thus arrayed in the unusual magnificence of purple and fine linen, and his roquelaure flaunting from his shoulders, he used to strut into the apartments of his patients, swaying his three-cornered hat in one hand, and his medical sceptre, the cane, in the other, and assuming an air of gravity and importance suited to the solemnity of his wig; at least, such is the picture given of him by the waiting-gentlewoman who let him into the chamber of one of his lady-patients.

He soon, however, grew tired and impatient of the duties and restraints of his profession; his practice was chiefly among his friends, and the fees were not sufficient for his maintenance; he was disgusted with attendance on sick-chambers and capricious patients, and looked back with longing to his tavern haunts and broad convivial meetings, from which the dignity and duties of his medical calling restrained him. At length, on prescribing to a lady of his acquaintance—who, to use a hackneyed phrase, “rejoiced” in the aristocratical name of Sidebotham—a warm dispute arose between him and the apothecary as to the quantity of medicine to be administered. The Doctor stood up for the rights and dignities of his profession, and resented the interference of the compounder of drugs. His rights and dignities, however, were disregarded; his wig and cane and scarlet roquelaure were of no avail; Mrs. Sidebotham sided with the hero of the pestle and mortar; and Goldsmith flung out of the house in a passion. “I am determined henceforth,” said he to Topham Beauclerc, “to leave off prescribing for friends.” “Do so, my dear doctor,” was the reply; “whenever you undertake to kill, let it be only your enemies.”

This was the end of Goldsmith’s medical career.

## CHAP. XVII.

Publication of the “Vicar of Wakefield”—Opinions concerning it—Of Dr. Johnson—Of Rogers the poet—Of Goethe—Its merits—Exquisite extract—Attack by Kenrick—Reply—Book-building—Project of a comedy.

The success of the poem of “The Traveller,” and the popularity which it had conferred on its author, now roused the attention of the bookseller in whose hands the novel of “The Vicar of Wakefield” had been slumbering for nearly two long years. The idea has generally prevailed that it was Mr. John Newbery to whom the manuscript had been sold, and much surprise has been expressed that he should be insensible to its merits, and suffer it to remain unpublished while putting forth various inferior writings by the same author. This, however, is a mistake; it was his nephew, Francis Newbery, who had become the fortunate purchaser. Still the delay is equally unaccountable. Some have imagined that the uncle and nephew had business arrangements together, in which this work was included, and that the elder Newbery, dubious of its success, retarded the publication until the full harvest of “The Traveller” should be reaped. Booksellers are prone to make egregious mistakes as to the merits of works in manuscript; and to undervalue, if not reject, those of classic and enduring excellence, when destitute of that false brilliancy commonly called “effect.” In the present instance, an intellect vastly superior to that of either of the booksellers was equally at fault. Dr. Johnson, speaking of the work to Boswell, some time subsequent to its publication, observed, “I myself did not think it would have had

much success. It was written and sold to a bookseller before ‘The Traveller,’ but published after, so little expectation had the bookseller from it. Had it been sold after ‘The Traveller,’ he might have had twice as much money; *though sixty guineas was no mean price.*”

Sixty guineas for the “Vicar of Wakefield!” and this could be pronounced *no mean price* by Dr. Johnson, at that time the arbiter of British talent, and who had an opportunity of witnessing the effect of the work upon the public mind; for its success was immediate. It came out on the 27th of March, 1766; before the end of May a second edition was called for; in three months more, a third; and so it went on, widening in popularity that has never flagged. Rogers, the Nestor of British literature, whose refined purity of taste and exquisite mental organization rendered him eminently calculated to appreciate a work of the kind, declared that of all the books which, through the fitful changes of three generations, he had seen rise and fall, the charm of the “Vicar of Wakefield” had alone continued as at first; and could he revisit the world after an interval of many more generations, he should as surely look to find it undiminished. Nor has its celebrity been confined to Great Britain. Though so exclusively a picture of British scenes and manners, it has been translated into almost every language, and everywhere its charm has been the same. Goethe, the great genius of Germany, declared, in his eighty-first year, that it was his delight at the age of twenty, that it had in a manner formed a part of his education, influencing his taste and feelings throughout life, and that he had recently read it again from beginning to end—with renewed delight, and with a grateful sense of the early benefit derived from it.

It is needless to expatiate upon the qualities of a work which has thus passed from country to country, and language to language, until it is now known throughout the whole reading world, and is become a household book in every hand. The secret of its universal and enduring popularity is undoubtedly the truth to nature, but to nature of the most amiable kind—to nature such as Goldsmith saw it. The author, as we have occasionally shown in the course of this memoir, took his scenes and characters in this, as in his other writings, from originals in his own motley experience; but he has given them as seen through the medium of his own indulgent eye, and has set them forth with the colourings of his own good head and heart. Yet how contradictory it seems that this, one of the most delightful pictures of home and homefelt happiness, should be drawn by a homeless man! that the most amiable pictures of domestic virtue, and all the endearments of the married state, should be drawn by a bachelor, who had been severed from domestic life almost from boyhood! that one of the most tender, touching, and affecting appeals on behalf of female loveliness should have been made by a man, whose deficiency in all the graces of person and manner seemed to mark him out for a cynical disparager of the sex!

We cannot refrain from transcribing from the work a short passage illustrative of what we have said, and which, within a wonderfully small compass, comprises a world of beauty of imagery, tenderness of feeling, delicacy and refinement of thought, and matchless purity of style. The two stanzas which conclude it, in which is told a whole history of woman’s wrongs and sufferings, are, for pathos, simplicity, and euphony, a gem in the language. The scene depicted is where the poor Vicar is gathering around him the wrecks of his shattered family, and endeavouring to rally them back to happiness.

“The next morning the sun arose with peculiar warmth for the season, so that we agreed to breakfast together on the honeysuckle bank; where, while we sat, my youngest daughter at my request joined her voice to the concert on the tree about us. It was in this place

my poor Olivia first met her seducer, and every object served to recal her sadness. But that melancholy which is excited by objects of pleasure, or inspired by sounds of harmony, soothes the heart instead of corroding it. Her mother, too, upon this occasion, felt a pleasing distress, and wept, and loved her daughter as before. 'Do, me pretty Olivia,' cried she, 'let us have that melancholy air your father was so fond of; your sister Sophy has already obliged us. Do, child, it will please your old father.' She complied in a manner so exquisitely pathetic as moved me.

When lonely woman stoops to folly,  
And finds too late that men betray,  
What charm can soothe her melancholy,  
What art can wash her guilt away.  
The only art her guilt to cover,  
To hide her shame from every eye,  
To give repentance to her lover,  
And wring his bosom—is to die.

Scarce had the "Vicar of Wakefield" made its appearance and been received with acclamation, than its author was subjected to one of the usual penalties that attend success. He was attacked in the newspapers. In one of the chapters he has introduced his ballad of "The Hermit," of which, as we have mentioned, a few copies had been printed some considerable time previously for the use of the Countess of Northumberland. This brought forth the following article in a fashionable journal of the day:—

*"To the Printer of the St. James's Chronicle."*

"SIR.—In the 'Reliques of Ancient Poetry,' published about two years ago, is a very beautiful little ballad, called 'A Friar of Orders Gray.' The ingenious editor, Mr. Percy, supposes that the stanzas sung by Ophelia in the play of Hamlet were parts of some ballad well known in Shakspeare's time, and from these stanzas, with the addition of one or two of his own to connect them, he has formed the above-mentioned ballad; the subject of which is, a lady comes to a convent to inquire for her lover, who had been driven there by her disdain. She is answered by a friar that he is dead—

No, no, he is dead, gone to his death's bed.  
He never will come again.

The lady weeps and laments her cruelty; the friar endeavours to comfort her with morality and religion, but all in vain; she expresses the deepest grief and the most tender sentiments of love, till at last the friar discovers himself—

And lo! beneath this gown of gray,  
Thy own true love appears.

"This catastrophe is very fine, and the whole, joined with the greatest tenderness, has the greatest simplicity; yet, though this ballad was so recently published in the 'Ancient Reliques,' Dr. Goldsmith has been hardy enough to publish a poem called 'The Hermit,' where the circumstance and catastrophe are exactly the same, only with this difference, that the natural simplicity and tenderness of the original are almost entirely lost in the languid smoothness and tedious paraphrase of the copy, which is as short of the merits of Mr. Percy's ballad as the insipidity of negus is to the genuine flavour of champagne.

"I am, sir, yours, &c.

"DETECTOR."

This attack, supposed to be by Goldsmith's constant persecutor, the malignant Kenrick, drew from him the following note to the editor:—

"SIR,—As there is nothing I dislike so much as newspaper controversy, particularly upon trifles, permit me to be as concise as possible in informing a correspondent of yours that I recommended 'Blainville's Travels' because I thought the book was a good one; and I think so still. I said I was told by the bookseller that it was then first published; but in that it seems I was mis-

informed, and my reading was not extensive enough to set me right.

"Another correspondent of yours accuses me of having taken a ballad I published some time ago from one by the ingenious Mr. Percy. I do not think there is any great resemblance between the two pieces in question. If there be any, his ballad was taken from mine. I read it to Mr. Percy some years ago; and he, as we both considered these things as trifles at best, told me, with his usual good humour, the next time I saw him, that he had taken my plan to form the fragments of Shakspeare into a ballad of his own. He then read me his little Cento, if I may so call it, and I highly approved it. Such petty anecdotes as these are scarce worth printing; were it not for the busy disposition of some of your correspondents, the public should never have known that he owes me the hint of his ballad, or that I am obliged to his friendship and learning for communications of a much more important nature.

"I am, sir, yours, &c.

"OLIVER GOLDSMITH."

The unexpected circulation of the "Vicar of Wakefield" enriched the publisher, but not the author. Goldsmith no doubt thought himself entitled to participate in the profits of the repeated editions; and a memorandum, still extant, shows that he drew upon Mr. Francis Newbery, in the month of June, for fifteen guineas, but that the bill was returned dishonoured. He continued, therefore, his usual job-work for the booksellers, writing introductions, prefaces, and head and tail pieces for new works; revising, touching up, and modifying travels and voyages; making compilations of prose and poetry, and "building books," as he sportively termed it. These tasks required little labour or talent, but that taste and touch which are the magic of gifted minds. His terms began to be proportioned to his celebrity. If his price was at any time objected to, "Why sir," he would say, "it may seem large; but then a man may be many years working in obscurity before his taste and reputation are fixed or estimated; and then he is, as in other professions, only paid for his previous labours."

He was, however, prepared to try his fortune in a different walk of literature from any he had yet attempted. We have repeatedly adverted to his fondness for the drama; he was a frequent attendant at the theatre; though, as we have shown, he considered them under gross management. He thought, too, that a vicious taste prevailed among those who wrote for the stage. "A new species of dramatic composition," says he, in one of his essays, "has been introduced under the name of *sentimental comedy*, in which the virtues of private life are exhibited rather than the vices exposed; and the distresses rather than the faults of mankind make our interest in the piece. In these plays almost all the characters are good, and exceedingly generous; they are lavish enough of their tin money on the stage; and though they want humour have abundance of sentiment and feeling. If they happen to have faults or foibles, the spectator is taught not only to pardon but to applaud them, in consideration of the goodness of their hearts; so that folly, instead of being ridiculed, is commended, and the comedy aims at touching our passions without the power of being truly pathetic. In this manner we are likely to lose one great source of an entertainment on the stage; for while the comic poet is invading the province of the tragic muse, he leaves her lively sister quite neglected. Of this, however, he is no ways solicitous, as he measures his fame by his profits. \* \* \*

"Humour, at present, seems to be departing from the stage; and it will soon happen that our comic players will have nothing left for it but a fine coat and a song. It depends upon the audience whether they will actually drive those poor merry creatures from the

stage, or sit at a play as gloomy as at the tabernacle. It is not easy to recover an art when once lost; and it will be a just punishment, that when, by our being too fastidious, we have banished humour from the stage, we should ourselves be deprived of the art of laughing."

Symptoms of reform in the drama had recently taken place. The comedy of the "Clandestine Marriage," the joint production of Colman and Garrick, and suggested by Hogarth's inimitable pictures of "Marriage-à-la-Mode," had taken the town by storm, crowded the theatre with fashionable audiences, and formed one of the leading literary topics of the year. Goldsmith's emulation was roused by its success. The comedy was in what he considered the legitimate line, totally different from the sentimental school; it presented pictures of real life—delineations of character and touches of humour, in which he felt himself calculated to excel. The consequence was, that in the course of the year (1766) he commenced a comedy of the same class, to be entitled the "Good-natured man," at which he diligently wrote whenever the hurried occupation of "book-building" allowed him leisure.

## CHAP. XVIII.

Social position of Goldsmith—His colloquial contests with Johnson—Anecdotes and Illustrations.

The social position of Goldsmith had undergone a material change since the publication of "The Traveller." Before that event he was but partially known as the author of some clever anonymous writings, and had been a tolerated member of the club and the Johnson circle, without much being expected from him. Now he had suddenly risen to literary fame, and become one of the lions of the day. The highest regions of intellectual society were now open to him; but he was not prepared to move in them with confidence and success. Ballymahon had not been a good school of manners at the outset of life; nor had his experience as a "poor student" at colleges and medical schools contributed to give him the polish of society. He had brought from Ireland, as he said, nothing but his "brogue and his blunders," and they had never left him. He had travelled, it is true; but the continental tour, which in those days gave the finishing grace to the education of a patrician youth, had with poor Goldsmith been little better than a course of literary vagabondising. It had enriched his mind, deepened and widened the benevolence of his heart, and filled his memory with enchanting pictures; but it had contributed little to disciplining him for the polite intercourse of the world. His life in London had hitherto been a struggle with sordid cares and sad humiliations. "You can scarcely conceive," wrote he some time previously to his brother, "how much eight years of disappointment, anguish, and study have worn me down." Several more years had since been added to the term during which he trod the lowly walks of life. He had been a tutor, an apothecary's drudge, a petty physician of the suburbs, a bookseller's hack, drudging for daily bread. Each separate walk had been beset by its peculiar thorns and humiliations. It is wonderful how his heart retained its gentleness and kindness through all these trials; how his mind rose above the "mean-nesses of poverty," to which, as he says, he was compelled to submit; but it would be still more wonderful had his manners acquired a tone corresponding to the innate grace and refinement of his intellect. He was near forty years of age when he published "The Traveller," and was lifted by it into celebrity. As is beautifully said of him by one of his biographers, "he has fought his way to consideration and esteem; but he bears upon him the scars of his twelve years' conflict; of the mean

sorrows through which he passed; and of the cheap indulgences he has sought relief and help from. There is nothing plastic in his nature now. His manners and habits are completely formed; and in them any further success can make little favourable change, whatever it may effect for his mind or genius."

We are not to be surprised, therefore, at finding him make an awkward figure in the elegant drawing-rooms which were now open to him, and disappointing those who had formed an idea of him from the fascinating ease and gracefulness of his poetry.

Even the Literary Club, and the circle of which it formed a part, after their surprise at the intellectual flights of which he had shown himself capable, fell into a conventional mode of judging and talking of him, and of placing him in absurd and whimsical points of view. His very celebrity operated here to his disadvantage. It brought him into continual comparison with Johnson, who was the oracle of that circle, and had given it a tone. Conversation was the great staple there, and of this Johnson was a master. He had been a reader and thinker from childhood; his melancholy temperament, which unfitted him for the pleasures of youth, had made him so. For many years past the vast variety of works he had been obliged to consult in preparing his Dictionary had stored an uncommonly retentive memory with facts on all kinds of subjects, making it a perfect colloquial armoury. "He had all his life," says Boswell, "habituated himself to consider conversation as a trial of intellectual vigour and skill. He had disciplined himself as a talker as well as a writer, making it a rule to impart whatever he knew in the most forcible language he could put it in, so that by constant practice, and never suffering any careless expression to escape him, he had attained an extraordinary accuracy and command of language.

His common conversation in all companies, according to Sir Joshua Reynolds, was such as to secure him universal attention, something above the usual colloquial style being always expected from him.

"I do not care," said Orme, the historian of Hindostan, "on what subject Johnson talks; but I love better to hear him talk than anybody. He either gives you new thoughts or a new colouring."

A stronger and more graphic eulogium is given by Dr. Percy:—"The conversation of Johnson," says he, "is strong and clear, and may be compared to an antique statue, where every vein and muscle is distinct and clear."

Such was the colloquial giant with which Goldsmith's celebrity and his habits of intimacy brought him into continual comparison; can we wonder that he should appear to disadvantage? Conversation grave, discursive, and disputations, such as Johnson excelled and delighted in, was to him a severe task, and he never was good at a task of any kind. He had not, like Johnson, a vast fund of acquired facts to draw upon, nor a retentive memory to furnish them forth when wanted. He could not, like the great lexicographer, mould his ideas and balance his periods while talking. He had a flow of ideas, but it was apt to be hurried and confused, and, as he said of himself, he had contracted a hesitating and disagreeable manner of speaking. He used to say that he always argued best when he argued alone; that is to say, he could master a subject in his study with his pen in his hand; but when he came into company he grew confused, and was unable to talk about it. Johnson made a remark concerning him to somewhat of the same purport. "No man," said he, "is more foolish than Goldsmith when he has not a pen in his hand, or more wise when he has." Yet, with all this conscious deficiency, he was continually getting involved in colloquial contests with Johnson and other prime talkers of the literary circle. He felt that he had become a notoriety—that he had entered the lists, and was expected to

make fight; so with that heedlessness which characterised him in everything else, he dashed on at a venture, trusting to chance in this as in other things, and hoping occasionally to make a lucky hit. Johnson perceived his hap-hazard temerity, but gave him no credit for the real diffidence that lay at bottom. "The misfortune of Goldsmith in conversation," said he, "is this—he goes on without knowing how he is to get off. His genius is great, but his knowledge is small. As they say of a generous man, it is a pity he is not rich, we may say of Goldsmith, it is a pity he is not knowing. He would not keep his knowledge to himself." And, on another occasion, he observes, "Goldsmith, rather than not talk, will talk of what he knows himself to be ignorant, which can only end in exposing him. If in company with two founders, he would fall a talking on the method of making cannon, though both of them would soon see that he did not know what metal a cannon is made of." And again—"Goldsmith should not be for ever attempting to shine in conversation; he has not a temper for it, he is so much mortified when he falls. Sir, a game of jokes is composed partly of skill, partly of chance; a man may be beat at times by one who has not the tenth part of his wit. Now Goldsmith, putting himself against another, is like a man laying a hundred to one who cannot spare the hundred. It is not worth a man's while. A man should not lay a hundred to one unless he can easily spare it, though he has a hundred chances for him; he can get but a guinea, and he may lose a hundred. Goldsmith is in this state. When he contends, if he gets the better, it is a very little addition to a man of his literary reputation; if he does not get the better, he is miserably vexed."

Johnson was not aware how much he was himself to blame in producing this vexation. "Goldsmith," said Miss Reynolds, "always appeared to be overawed by Johnson, particularly when in company with people of any consequence—always as if impressed with fear of disgrace; and, indeed, well he might. I have been witness to many mortifications he has suffered in Dr. Johnson's company."

It may not have been disgrace that he feared, but rudeness. The great lexicographer, spoiled by the homage of society, was still more prone than himself to lose temper when the argument went against him. He could not brook appearing to be worsted, but would attempt to bear down his adversary by the rolling thunder of his periods; and when that failed would become downright insulting. Boswell called it "having recourse to some sudden mode of robust sophistry;" but Goldsmith designated it much more happily. "There is no arguing with Johnson," said he, "*for, when his pistol misses fire, he knocks you down with the butt-end of it.*"

In several of the intellectual collisions recorded by Boswell as triumphs of Dr. Johnson, it really appears to us that Goldsmith had the best, both of the wit and the argument, and especially of the courtesy and good-nature.

On one occasion he certainly gave Johnson a capital reproof as to his own colloquial peculiarities. Talking of fables, Goldsmith observed that the animals introduced in them seldom talked in character. "For instance," said he, "the fable of the little fishes who saw birds fly over their heads, and, envying them, petitioned Jupiter to be changed into birds. The skill consists in making them talk like little fishes." Just then, observing that Dr. Johnson was shaking his sides and laughing, he immediately added, "why, Dr. Johnson, this is not so easy as you seem to think; for, if you were to make little fishes talk, they would talk like whales."

\* The following is given by Boswell, as an instance of robust sophistry:—"Once, when I was pressing upon him with visible advantage, he stopped me thus—'My dear Boswell, let's have no more of this; you'll make nothing of it. I'd rather hear you whistle a Scotch tune.'"

But though Goldsmith suffered frequent mortifications in society from the overbearing, and sometimes harsh, conduct of Johnson, he always did justice to his benevolence. When royal pensions were granted to Dr. Johnson and Dr. Shebbeare, a punster remarked that the king had pensioned a *she-bear* and a *he-bear*; to which Goldsmith replied, "Johnson, to be sure, has a roughness in his manner, but no man alive has a more tender heart. *He has nothing of the bear but the skin.*"

Goldsmith, in conversation, shone most when he least thought of shining—when he gave up all effort to appear wise and learned, or to cope with the oracular sententiousness of Johnson, and gave way to his natural impulses. Even Boswell could perceive his merits on these occasions. "For my part," said he, condescendingly, "I like very well to hear honest Goldsmith talk away carelessly;" and many a much wiser man than Boswell delighted in those outpourings of a fertile fancy and a generous heart. In his happy moods Goldsmith had an artless simplicity and buoyant good-humour that led to a thousand amusing blunders and whimsical confessions, much to the entertainment of his intimates; yet, in his most thoughtless garrulity, there was occasionally the gleam of the gold and the flash of the diamond.

## CHAP. XIX.

Social resorts—The shilling whist-club—A practical joke—The Wednesday club—The "tun-man"—The pig-butcher—Tom King—Hugh Kelly—Glover and his characteristics.

Though Goldsmith's pride and ambition led him to mingle occasionally with high society, and to engage in the colloquial conflicts of the learned circle, in both of which he was ill at ease and conscious of being undervalued, yet he had some social resorts in which he indemnified himself for their restraints by indulging his humour without control. One of them was a shilling whist-club, which held its meeting at the Devil Tavern, near Temple Bar, a place rendered classic, we are told, by a club held there in old times, to which "Rare Ben Jonson" had furnished the rules. The company was of a familiar, unceremonious kind, delighting in that very questionable wit which consists in playing off practical jokes upon each other. Of one of these Goldsmith was made the butt. Coming to the club one night in a hackney coach, he gave the coachman by mistake a guinea instead of a shilling, which he set down as a dead loss, for there was no likelihood, he said, that a fellow of this class would have the honesty to return the money. On the next club evening he was told a person at the street door wished to speak with him. He went forth, but soon returned with a radiant countenance. To his surprise and delight the coachman had actually brought back the guinea. While he launched forth in praise of this unlooked for piece of honesty, he declared it ought not to go unrewarded. Collecting a small sum from the club, and no doubt increasing it largely from his own purse, he dismissed the Jehu with many encomiums on his good conduct. He was still chanting his praises, when one of the club requested a sight of the guinea thus honestly returned. To Goldsmith's confusion, it proved to be a counterfeit. The universal burst of laughter which succeeded, and the jokes by which he was assailed on every side, showed him that the whole was a hoax, and the pretended coachman as much a counterfeit as the guinea. He was so disconcerted, it is said, that he soon beat a retreat for the evening.

Another of these free-and-easy clubs met on Wednesday evenings at the Globe Tavern, in Fleet-street. It was somewhat in the style of the Three Jolly Pigeons;

songs, jokes, dramatic imitations, burlesque parodies, and broad sallies of humour, formed a contrast to the sententious morality, pedantic casuistry, and polished sarcasm of the learned circle. Here a huge "tun of man," by the name of Gordon, used to delight Goldsmith by singing the jovial song of "Nottingham Ale," and looking like a butt of it. Here, too, a wealthy pig-butcher, charmed, no doubt, by the mild philanthropy of "The Traveller," aspired to be on the most social footing with the author; and here was Tom King, the comedian, recently risen in consequence by his performance of Lord Ogleby, in the new comedy of "The Clandestine Marriage."

A member of more note was one Hugh Kelly, a second-rate author, who, as he became a kind of competitor of Goldsmith's, deserves particular mention. He was an Irishman about twenty-eight years of age, originally apprenticed to a staymaker in Dublin; then writer to a London attorney; then a Grubb-street hack, scribbling for magazines and newspapers. At length he had set up for theatrical censor and satirist; and in a paper called "Thespis," in emulation of Churchill's "Rosciad," had harassed many of the poor actors without mercy, and often without wit; but had lavished his incense on Garrick, who, in consequence, took him into favour. He was the author of several works of superficial merit, but which had sufficient vogue to inflate his vanity. This, however, must have been mortified on his first introduction to Johnson; after sitting a short time he got up to take leave, expressing a fear that a longer visit might be troublesome. "Not in the least, sir," said the surly moralist; "I had forgotten you were in the room." Johnson used to speak of him as a man who had written more than he had read.

A prime wag of this club was one of Goldsmith's poor countrymen and hangers-on, by the name of Glover. He had originally been educated for the medical profession, but had taken in early life to the stage, though apparently without much success. While performing at Cork, he undertook, partly in jest, to restore life to the body of a malefactor who had just been executed. To the astonishment of every one, himself among the number, he succeeded. The miracle took wind. He abandoned the stage, resumed his wig and cane, and considered his fortune as secure. Unluckily, there were not many people to be restored to life in Ireland; his practice did not equal his expectation, so he came to London, where he continued to dabble indifferently, and rather unprofitably, in physic and literature.

He was a great frequenter of the Globe and Devil taverns, where he used to amuse the company by his talent at story-telling and his powers of mimicry, giving capital imitations of Garrick, Foote, Colman, Sterne, and other public characters of the day. He seldom happened to have money enough to pay his reckoning, but was always sure to find some ready purse among those who had been amused by his humours. Goldsmith, of course, was one of the readiest. It was through him that Glover was admitted to the Wednesday Club, of which his theatrical imitations became the delight. Glover, however, was a little anxious for the dignity of his patron, which appeared to him to suffer from the over-familiarity of some of the members of the club. He was especially shocked by the free-and-easy tone in which Goldsmith was addressed by the pig-butcher. "Come, Noll," would he say, as he pledged him, "here's my service to you, old boy!"

Glover whispered to Goldsmith that he "should not allow such liberties." "Let him alone," was the reply, "you'll see how civilly I'll let him down." After a time he called out, with marked ceremony and politeness, "Mr. B., I have the honour of drinking your good health." Alas! dignity was not poor Goldsmith's forte: he could keep no one at a distance. "Thank'ee, thank'ee, Noll," nodded the pig-butcher, scarce taking the pipe

out of his mouth. "I don't see the effect of your reproof," whispered Glover. "I give it up," replied Goldsmith, with a good-humoured shrug; "I ought to have known before now there is no putting a pig in the right way."

Johnson used to be severe upon Goldsmith for mingling in these motley circles, observing, that having been originally poor, he had contracted a love for low company. Goldsmith, however, was guided, not by a taste for what was low, but for what was comic and characteristic. It was the feeling of the artist—the feeling which furnished out some of his best scenes in familiar life—the feeling with which "Rare Ben Jonson" sought these very haunts and circles in days of yore, to study "Every Man in his Humour."

It was not always, however, that the humour of these associates was to his taste; as they became boisterous in their merriment, he was apt to become depressed. "The company of fools," says he, in one of his essays, "may at first make us smile; but at last never fails of making us melancholy."—"Often he would become moody," says Glover, "and would leave the party abruptly, to go home and brood over his misfortune."

It is possible, however, that he went home for quite a different purpose—to commit to paper some scene or passage suggested for his comedy of "The Good-natured Man." The elaboration of humour is often a most serious task; and we have never witnessed a more perfect picture of mental misery than was once presented to us by a popular dramatic writer—still, we hope, living—whom we found in the agonies of producing a farce, which subsequently set the theatres in a roar.

## CHAP. XX.

The great Cham of literature and the King—Scene at Sir Joshua Reynolds's—Goldsmith accused of jealousy—Negotiations with Garrick—The author and the actor—Their correspondence.

The comedy of "The Good-natured Man" was completed by Goldsmith early in 1767, and submitted to the perusal of Johnson, Burke, Reynolds, and others of the literary club, by whom it was heartily approved. Johnson, who was seldom half way, either in censure or applause, pronounced it the best comedy that had been written since "The Provoked Husband," and promised to furnish the prologue. This immediately became an object of great solicitude with Goldsmith, knowing the weight an introduction from the Great Cham of literature would have with the public; but circumstances occurred which he feared might drive the comedy and the prologue from Johnson's thoughts. The latter was in the habit of visiting the royal library at the Queen's (Buckingham) House—a noble collection of books, in the formation of which he had assisted the librarian, Mr. Bernard, with his advice. One evening, as he was seated there by the fire reading, he was surprised by the entrance of the King (George III.), then a young man, who sought this occasion to have a conversation with him. The conversation was varied and discursive, the King shifting from subject to subject according to his wont. "During the whole interview," says Boswell, "Johnson talked to his majesty with profound respect, but still in his open, manly manner, with a sonorous voice, and never in that subdued tone, which is commonly used at the levee and in the drawing-room. 'I found his majesty wished I should talk,' said he, 'and I made it my business to talk. I find it does a man good to be talked to by his sovereign. In the first place, a man cannot be in a passion.' It would have been as well for Johnson's colloquial disputants could he have often been under such decorous restraint. Profoundly monarchical in his principles, he retired from the interview highly gratified with the conversation of the King,

and with his gracious behaviour. "Sir," said he to the librarian, "they may talk of the King as they will, but he is the finest gentleman I have ever seen."—"Sir," said he, subsequently, to Bennet Langton, "his manners are those of as fine a gentleman as we may suppose Louis the Fourteenth or Charles the Second."

While Johnson's face was still radiant with the reflex of royalty, he was holding forth one day to a listening group at Sir Joshua Reynolds's, who were anxious to hear every particular of this memorable conversation. Among other questions, the King had asked him whether he was writing anything. His reply was, that he thought he had already done his part as a writer. "I should have thought so too," said the King, "if you had not written so well."—"No man," said Johnson, commenting on this speech, "could have made a handsomer compliment; and it was fit for a king to pay. It was decisive."—"But did you make no reply to this high compliment?" asked one of the company. "No, sir," replied the profoundly deferential Johnson, "when the King had said it, it was to be so. It was not for me to bandy civilities with my sovereign."

During all the time that Johnson was thus holding forth, Goldsmith, who was present, appeared to take no interest in the royal theme, but remained seated on a sofa at a distance, in a moody fit of abstraction; at length, recollecting himself, he sprang up, and advancing, exclaimed, with what Boswell calls his usual "frankness and simplicity," "Well, you acquitted yourself in this conversation better than I should have done, for I should have bowed and stammered through the whole of it." He afterwards explained his seeming inattention, by saying that his mind was completely occupied about his play, and by fears lest Johnson, in his present state of royal excitement, would fail to furnish the much-desired prologue.

How natural and truthful is this explanation! Yet Boswell presumes to pronounce Goldsmith's inattention affected; and attributes it to jealousy. "It was strongly suspected," says he, "that he was fretting with chagrin and envy at the singular honour Dr. Johnson had lately enjoyed." It needed the littleness of mind of Boswell to ascribe such pitiful motives to Goldsmith, and to entertain such exaggerated notions of the honour paid to Dr. Johnson.

"The Good-natured Man" was now ready for performance, but the question was, how to get it on the stage. The affairs of Covent Garden, for which it had been intended, were thrown into confusion by the recent death of Rich, the manager. Drury Lane was under the management of Garrick, but a feud, it will be recollected, existed between him and the poet, from the animadversions of the latter on the mismanagement of theatrical affairs, and the refusal of the former to give the poet his vote for the secretaryship of the Society of Arts. Times, however, were changed. Goldsmith, when that feud took place, was an anonymous writer, almost unknown to fame, and of no circulation in society. Now he had become a literary lion; he was a member of the Literary Club; he was the associate of Johnson, Burke, Topham Beauclerc, and other magnates—in a word, he had risen to consequence in the public eye, and of course was of consequence in the eye of David Garrick. Sir Joshua Reynolds saw the lurking scruples of pride existing between the author and the actor, and thinking it a pity that two men of such congenial talents, and who might be so serviceable to each other, should be kept asunder by a worn-out pique, exerted his friendly offices to bring them together. The meeting took place in Reynolds's house in Leicester-square. Garrick, however, could not entirely put off the mock-majesty of the stage; he meant to be civil, but he was rather too gracious and condescending. Tom Davies, in his "Life of Garrick," gives an amusing picture of the coming together of these punctilious parties. "The manager,"

says he, "was fully conscious of his (Goldsmith's) merit, and perhaps more ostentatious of his abilities to serve a dramatic author than became a man of his prudence; Goldsmith was, on his side, as fully persuaded of his own importance and independent greatness. Mr. Garrick, who had so long been treated with the complimentary language paid to a successful patentee and admired actor, expected that the writer would esteem the patronage of his play a favour; Goldsmith rejected all idea of kindness in a bargain that was intended to be of mutual advantage to both parties—and in this he was certainly justifiable; Mr. Garrick could reasonably expect no thanks for the acting a new play, which he would have rejected if he had not been convinced it would have amply rewarded his pains and expense. I believe the manager was willing to accept the play, but he wished to be courted to it; and the doctor was not disposed to purchase his friendship by the resignation of his sincerity." They separated, however, with an understanding on the part of Goldsmith that his play would be acted. The conduct of Garrick subsequently proved evasive, not through any lingering of past hostility, but from habitual indecision in matters of the kind, and from real scruples and delicacy. He did not think the piece likely to succeed on the stage, and avowed that opinion to Reynolds and Johnson; but hesitated to say as much to Goldsmith, through fear of wounding his feelings. A further misunderstanding was the result of this want of decision and frankness; repeated interviews and some correspondence took place without bringing matters to a point, and in the meantime the theatrical season passed away.

Goldsmith's pocket, never well supplied, suffered grievously by this delay, and he considered himself entitled to call upon the manager, who still talked of acting the play, to advance him forty pounds upon a note of the younger Newbery. Garrick readily complied, but subsequently suggested certain important alterations in the comedy as indispensable to its success; these were indignantly rejected by the author, but pertinaciously insisted on by the manager. Garrick proposed to leave the matter to the arbitration of Whitehead, the laureate, who officiated as his "reader" and elbow-critic. Goldsmith was more indignant than ever, and a violent dispute ensued, which was only calmed by the interference of Burke and Reynolds.

Just at this time order came out of confusion in the affairs of Covent Garden. A pique having arisen between Colman and Garrick, in the course of their joint authorship of "The Clandestine Marriage," the former had become manager and part-proprietor of Covent Garden, and was preparing to open a powerful competition with his former colleague. On hearing of this, Goldsmith made overtures to Colman, who, without waiting to consult his fellow-proprietors, who were absent, gave instantly a favourable reply. Goldsmith felt the contrast of this warm, encouraging conduct, to the chilling delays and objections of Garrick. He at once abandoned his piece to the discretion of Colman. "Dear sir," says he, in a letter dated Temple-garden-court, July 9th, "I am very much obliged to you for your kind partiality in my favour, and your tenderness in shortening the interval of my expectation. That the play is liable to many objections I well know, but I am happy that it is in hands the most capable in the world of removing them. If, then, dear sir, you will complete your favour by putting the piece into such a state as it may be acted, or of directing me how to do it, I shall ever retain a sense of your goodness to me. And indeed, though most probably this may be the last I shall ever write, yet I can't help feeling a secret satisfaction that poets for the future are likely to have a protector who declines taking advantage of their dreadful situation, and scorns that importance which may be acquired by trifling with their anxieties."

The next day Goldsmith wrote to Garrick, who was at Lichfield, informing him of his having transferred his piece to Covent Garden, for which it had been originally written, and by the patentee of which it was claimed, observing, "As I found you had very great difficulties about that piece, I complied with his desire. \* \*

\* \* I am extremely sorry that you should think me warm at our last meeting; your judgment certainly ought to be free, especially in a matter which must in some measure concern your own credit and interest. I assure you, sir, I have no disposition to differ with you on this or any other account, but am, with a high opinion of your abilities, and a very real esteem, sir, your most obedient humble servant,

"OLIVER GOLDSMITH."

In his reply Garrick observed, "I was, indeed, much hurt that your warmth at our last meeting mistook my sincere and friendly attention to your play for the remains of a former misunderstanding, which I had as much forgot as if it had never existed. What I said to you at your own house I now repeat, that I felt more pain in giving my sentiments than you possibly would in receiving them. It has been the business, and ever will be, of my life to live on the best terms with men of genius; and I know that Dr. Goldsmith will have no reason to change his previous friendly disposition towards me, as I shall be glad of every future opportunity to convince him how much I am his obedient servant and well-wisher. D. GARRICK."

#### CHAP. XXI.

More hack authorship—Tom Davies and the Roman History—Canonbury Castle—Political authorship—Pecuniary temptation—Death of Newbery the elder.

Though Goldsmith's comedy was now in train to be performed, it could not be brought out before Christmas; in the meantime, he must live. Again, therefore, he had to resort to literary jobs for his daily support. These obtained for him petty occasional sums, the largest of which was ten pounds, from the elder Newbery, for an historical compilation; but this scanty rill of *quasi* patronage, so sterile in its products, was likely soon to cease—Newbery being too ill to attend to business, and having to transfer the whole management of it to his nephew.

At this time Tom Davies, the sometime Roscius, sometime bibliopole, stepped forward to Goldsmith's relief, and proposed that he should undertake an easy popular history of Rome in two volumes. An arrangement was soon made. Goldsmith undertook to complete it in two years, if possible, for two hundred and fifty guineas, and forthwith set about his task with cheerful alacrity. As usual, he sought a rural retreat during the summer months, where he might alternate his literary labours with strolls about the green fields. "Merry Islington" was again his resort; but he now aspired to better quarters than formerly, and engaged the chambers occupied occasionally by Mr. Newbery, in Canonbury House, or Castle, as it is popularly called. This had been a hunting-lodge of Queen Elizabeth, in whose time it was surrounded by parks and forests. In Goldsmith's day nothing remained of it but an old brick tower; it was still in the country, amid rural scenery, and was a favourite nestling-place of authors, publishers, and others of the literary order.\* A number of these he had for

fellow-occupants of the castle, and they formed a temporary club, which held its meetings at the Crown Tavern, on the Islington lower road; and here he presided in his own genial style, and was the life and delight of the company.

The writer of these pages visited old Canonbury Castle some years since, out of regard to the memory of Goldsmith. The apartment was still shown which the poet had inhabited, consisting of a sitting-room and small bedroom, with paneled wainscots and Gothic windows. The quaintness and quietude of the place were still attractive. It was one of the resorts of citizens on their Sunday walks, who would ascend to the top of the tower and amuse themselves with reconnoitring the city through a telescope. Not far from this tower were the gardens of the White Conduit House, a Cockney elysium, where Goldsmith used to figure in the humbler days of his fortune. In the first edition of his *Essays* he speaks of a stroll in these gardens, where he at that time, no doubt, thought himself in perfect genteel society. After his rise in the world, however, he became too knowing to speak of such plebeian haunts. In a new edition of his *Essays*, therefore, the White Conduit House and its garden disappear, and he speaks of "a stroll in the Park."

While Goldsmith was literally living from hand to mouth by the forced drudgery of the pen, his independence of spirit was subjected to a sore pecuniary trial. It was the opening of Lord North's administration, a time of great political excitement. The public mind was agitated by the question of American taxation, and other questions of like irritating tendency. Junius and Wilkes and other powerful writers were attacking the administration with all their force; Grubb-street was stirred up to its lowest depths; inflammatory talent of all kinds was in full activity, and the kingdom was deluged with pamphlets, lampoons, and libels of the grossest kind. The ministry were looking anxiously round for literary support. It was thought that the pen of Goldsmith might be readily enlisted. His hospitable friend and countryman, Lord Nugent, politically known as Squire Gawky, had come out strenuously for local taxation; had been selected for a lordship of the board of trade, and raised to the rank of Baron Nugent and Viscount Clare. His example, it was thought, would be enough of itself to bring Goldsmith into the ministerial ranks; and then what writer of the day was proof against a full purse or a pension? Accordingly, one Parson Scott, chaplain to Lord Sandwich, and author of "Anti-Sejanus Panurge," and other political libels in support of the administration, was sent to negotiate with the poet, who at this time was returned to town. Dr. Scott, in after years, when his political subserviency had been rewarded by two fat crown livings, used to make what he considered a good story out of this embassy to the poet. "I found him," said he, "in a miserable suite of chambers in the Temple. I told him my authority. I told how I was empowered to pay most liberally for his exertions; and, would you believe it! he was so absurd as to say 'I can earn as much as will supply my wants without writing for any party; the assistance you offer is therefore unnecessary to me'—and so I left him in his garret!" Who does not admire the sturdy independence of poor Goldsmith, toiling in his garret for nine guineas the job, and smile with contempt at the indignant wonder of the political divine, albeit his subserviency was repaid by two fat crown livings.

Not long after this occurrence, Goldsmith's old friend, though frugal-handed employer, Newbery, of picture-book renown, closed his mortal career. The poet has celebrated him as the friend of all mankind; he certainly lost nothing by his friendship. He coined the brains of his authors in the times of their exigency, and made them pay dear for the plank put out to keep them

\* See on the distant slope, majestic shows  
Old Canonbury's tower, an ancient pile  
To various fates assigned; and where by turns  
Meanness and grandeur have alternate reigned.  
Thither, in latter days, hath genius fled  
From yonder city, to respire and die.  
There the sweet bard of Auburn sat, and tuned  
The plaintive moanings of his village dirge.  
There learned Chambers treasured lore for men,  
And Newbery there his A B C's for babes.

from drowning. It is not likely his death caused much lamentation among the scribbling tribe; we may express decent respect for the memory of the just, but we shed tears only at the grave of the generous.

## CHAP. XXII.

Theatrical manœuvring—The comedy of "False Delicacy"—First performance of the "Good-natured Man"—Conduct of Johnson—Conduct of the author—Intermeddling of the press.

The comedy of "The Good-natured Man" was doomed to experience delays and difficulties to the very last. Garrick, notwithstanding his professions, had still a lurking grudge against the author, and tasked his managerial arts to thwart him in his theatrical enterprise. For this purpose he undertook to build up Hugh Kelly, Goldsmith's boon companion of the Wednesday club, as a kind of rival. Kelly had written a comedy called "False Delicacy," in which were embodied all the meretricious qualities of the sentimental school. Garrick, though he had decried that school, and had brought out his comedy of the "Clandestine Marriage" in opposition to it, now lauded "False Delicacy" to the skies, and prepared to bring it out at Drury Lane with all possible stage effect. He even went so far as to write a prologue and epilogue for it, and to touch up some parts of the dialogue. He had become reconciled to his former colleague, Colman, and it is intimated one condition in the treaty of peace between these potentates in the realms of pasteboard (equally prone to play into each other's hands with the confederate potentates on the great theatre of life) was, that Goldsmith's play should be kept back until Kelly's had been brought forward.

In the meantime the poor author, little dreaming of the deleterious influence at work behind the scenes, saw the appointed time arrive and pass by without the performance of his play; while "False Delicacy" was brought out at Drury Lane (January 28, 1768) with all the trickery of managerial management. Houses were packed to applaud it to the echo; the newspapers vied with each other in their venal praises, and night after night seemed to give it a fresh triumph.

While "False Delicacy" was thus borne on the full tide of fictitious prosperity, "The Good-natured Man" was creeping through the last rehearsals at Covent Garden. The success of the rival piece threw a damp upon author, manager, and actors. Goldsmith went about with a face full of anxiety; Colman's hopes in the piece declined at each rehearsal; as to his fellow-proprietors, they declared they had never entertained any. All the actors were discontented with their parts, excepting Ned Shuter, an excellent low-comedian, and a pretty actress named Miss Walford; both of whom the poor author ever afterward held in grateful recollection.

Johnson, Goldsmith's growling monitor and unsparing castigator in times of heedless levity, stood by him at present with that protecting kindness with which he ever befriended him in time of need. He attended the rehearsals; he furnished the prologue according to promise; he pish'd and pshaw'd at any doubts and fears on the part of the author, but gave him sound counsel, and helped him up with a steadfast and manly hand. Inspired by his sympathy, Goldsmith plucked up new heart, and arrayed himself for the grand trial with unusual care. Ever since his elevation into the polite world, he had improved in his wardrobe and toilet. Johnson could no longer accuse him of being shabby in his appearance; he rather went to the other extreme. On the present occasion there is an entry in the books of his tailor, Mr. William Filby, of a suit of "Tyrian bloom, satin grain, and garter blue silk breeches,

£8 2s. 7d." Thus magnificently attired he attended the theatre, and watched the reception of the play and the effect of each individual scene with that vicissitude of feeling incident to his mercurial nature."

Johnson's prologue was solemn in itself, and being delivered by Brinsley in lugubrious tones, suited to the Ghost in "Hamlet," seemed to throw a portentous gloom on the audience. Some of the scenes met with great applause, and at such times Goldsmith was highly elated; others went off coldly, or there were slight tokens of disapprobation, and then his spirits would sink. The fourth act saved the piece; for Shuter, who had the main comic character of Croaker, was so varied and ludicrous in his execution of the scene in which he reads an incendiary letter, that he drew down thunders of applause. On his coming behind the scenes, Goldsmith greeted him with an overflowing heart; declaring that he exceeded his own idea of the character, and made it almost as new to him as to any of the audience.

On the whole, however, both the author and his friends were disappointed at the reception of the piece, and considered it a failure. Poor Goldsmith left the theatre with his towering hopes completely cut down. He endeavoured to hide his mortification, and even to assume an air of unconcern while among his associates; but the moment he was alone with Dr. Johnson, in whose rough and magnanimous nature he reposed unlimited confidence, he threw off all restraint, and gave way to an almost child-like burst of grief. Johnson, who had shown no want of sympathy at the proper time, saw nothing in the partial disappointment of over-rated expectations to warrant such ungoverned emotions, and rebuked him sternly for what he termed a silly affectation, saying that "no man should be expected to sympathise with the sorrows of vanity."

When Goldsmith had recovered from the blow, he, with his usual unreserve, made his past distress a subject of amusement to his friends. Dining one day, in company with Dr. Johnson, at the chaplain's table at St. James's Palace, he entertained the company with a particular and comic account of all his feelings on the night of representation, and his despair when the piece was hissed. How he went, he said, to the Literary Club; chatted gaily, as if nothing had gone amiss; and to give a greater idea of his unconcern, sang his favourite song about an old woman tossed in a blanket seventeen times as high as the moon. . . . "All this while," added he, "I was suffering horrid tortures, and, had I put a bit in my mouth, I verily believe it would have strangled me on the spot, I was so excessively ill; but I made more noise than usual to cover all that; so they never perceived my not eating, nor suspected the anguish of my heart; but when all were gone except Johnson here, I burst out a-crying, and even swore that I would never write again."

Dr. Johnson sat in a maze at the old frankness and childlike self-accusation of poor Goldsmith. When the latter came to a pause, "All this, doctor," said he, drily, "I thought had been a secret between you and me, and I am sure I would not have said anything about it for the world." But Goldsmith had no secrets: his follies, his weaknesses, his errors, were all thrown to the surface; his heart was really too guileless and innocent to seek mystery and concealment. It is too often the false, designing man that is guarded in his conduct, and never offends proprieties.

It is singular, however, that Goldsmith, who thus in conversation could keep nothing to himself, should be the author of a maxim which would inculcate the most thorough dissimulation. "Men of the world," says he, in one of the papers of the "Bee," "maintain that the true end of speech is not so much to express our wants as to conceal them." How often is this quoted as one of the subtle remarks of the fine-witted Talleyrand!

"The Good-natured Man" was performed for ten

nights in succession; the third, sixth, and ninth nights were for the author's benefit; the fifth night it was commanded by their majesties; after this it was played occasionally, but rarely, having always pleased more in the closet than on the stage.

As to Kelly's comedy, Johnson pronounced it entirely devoid of character, and it has long since passed into oblivion. Yet it is an instance how far an inferior production, by dint of puffing and trumpeting, may be kept up for a time on the surface of popular opinion, or rather of popular talk. What had been done for "False Delicacy" on the stage was continued by the press. The booksellers vied with the manager in launching it upon the town. They announced that the first impression of three thousand copies was exhausted before two o'clock on the day of publication; four editions, amounting to ten thousand copies, were sold in the course of the season; a public breakfast was given to Kelly at the Chapter Coffee-house, and a piece of plate presented to him by the publishers. The comparative merits of the two plays were continually subjects of discussion in green-rooms, coffee-houses, and other places where theatrical questions were discussed.

Goldsmith's old enemy, Kenrick, that "viper of the press," endeavoured on this, as on many other occasions, to detract from his well-earned fame; the poet was excessively sensitive to these attacks, and had not the art and self-command to conceal his feelings.

Some scribblers on the other side insinuated that Kelly had seen the manuscript of Goldsmith's play, while in the hands of Garrick or elsewhere, and had borrowed some of the situations and sentiments. Some of the wags of the day took a mischievous pleasure in stirring up a feud between the two authors. Goldsmith became nettled, though he could scarcely be deemed jealous of one so far his inferior. He spoke disparagingly, though no doubt sincerely, of Kelly's play: the latter retorted. Still, when they met one day behind the scenes at Covent Garden, Goldsmith, with his customary urbanity, congratulated Kelly on his success. "If I thought you sincere, Mr. Goldsmith," replied the other, abruptly, "I should thank you." Goldsmith was not a man to harbour spleen or ill-will, and soon laughed at this unworthy rivalry; but the jealousy and envy awakened in Kelly's mind long continued. He is even accused of having given vent to his hostility by anonymous attacks in the newspapers—the basest resource of dastardly and malignant spirits; but of this there is no positive proof.

### CHAP. XXIII.

Burning the candle at both ends—Fine apartments, fine furniture, fine clothes, fine acquaintances—Shoemakers' holiday and "Jolly Pigeon" associates—Peter Barlow, Glover, and the Hampstead hoax—Poor friends among great acquaintances.

The profits resulting from "The Good-natured Man" were beyond any that Goldsmith had yet derived from his works. He netted about four hundred pounds from the theatre, and one hundred pounds from his publisher.

Five hundred pounds! and all at one miraculous draught! It appeared to him wealth inexhaustible. It at once opened his heart and hand, and led him into all kinds of extravagance. The first symptom was ten guineas to Shuter for a box ticket for his benefit, when the "Good-natured Man" was to be performed. The next was an entire change of his domicile. The shabby lodgings with Jeffs, the butler, in which he had been worried by Johnson's scrutiny, were now exchanged for chambers more becoming a man of his ample fortune. The apartments consisted of three rooms on the second floor of No. 2, Brick-court, Middle Temple, on the right

hand ascending the staircase, and over-looked the umbrageous walks of the Temple-garden. The lease he purchased for four hundred pounds, and then went on to furnish his rooms with mahogany sofas, card-tables, and bookcases; with curtains, mirrors, and Wilton carpets. His awkward little person was also furnished out in a style befitting his apartment; for, in addition to his suit of "Tyrian bloom, satin grain," we find another charged about this time, in the books of Mr. Filby, in no less gorgeous terms, being "lined with silk and furnished with gold buttons." Thus lodged, and thus arrayed, he invited the visits of his most aristocratic acquaintances, and no longer quailed beneath the courtly eye of Beauclerc. He gave dinners to Johnson, Reynolds, Percy, Bickerstaff, and other friends of note; and supper parties to young folks of both sexes. These last were preceded by round games of cards, at which there was more laughter than skill, and in which the sport was to cheat each other; or by romping games of forfeits and blindman's-buff, at which he enacted the lord of misrule. Blackstone, whose chambers were immediately below, and who was studiously occupied on his "Commentaries," used to complain of the racket made over-head by his revelling neighbour.

Sometimes Goldsmith would make up a rural party, composed of four or five of his "Jolly Pigeon" friends, to enjoy what he humorously called a "shoemakers' holiday." These would assemble at his chambers in the morning to partake of a plentiful and rather expensive breakfast; the remains of which, with his customary benevolence, he generally gave to some poor woman in attendance. The repast ended, the party would set out on foot, in high spirits, making extensive rambles by foot-paths and green lanes to Blackheath, Wandsworth, Chelsea, Hampton Court, Highgate, or some other pleasant resort within a few miles of London. A simple but gay and heartily-relished dinner at a country inn crowned the excursion. In the evening they strolled back to town, all the better in health and spirits for a day spent in rural and social enjoyment. Occasionally, when extravagantly inclined, they adjourned from dinner to drink tea at the White Conduit House; and, now and then, concluded their festive day by supping at the Grecian or Temple Exchange Coffee houses, or at the Globe Tavern in Fleet-street. The whole expenses of the day never exceeded a crown, and were oftener from three and sixpence to four shillings; for the best part of their entertainment—sweet air and rural scenes, excellent exercise and joyous conversation—cost nothing.

One of Goldsmith's humble companions on these excursions was his occasional amanuensis Peter Barlow, whose quaint peculiarities afforded much amusement to the company. Peter was poor but punctilious, squaring his expenses according to his means. He always wore the same garb; fixed his regular expenditure for dinner at a trifling sum, which, if left to himself, he never exceeded, but which he always insisted on paying. His oddities always made him a welcome companion on the "shoemakers' holidays." The dinner on these occasions generally exceeded considerably his tariff; he put down, however, no more than his regular sum, and Goldsmith made up the difference.

Another of these hangers-on, for whom, on such occasions, he was content to "pay the shot," was his countryman Glover, of whom mention has already been made as one of the wags and sponges of the Globe and Devil taverns, and a prime mimic at the Wednesday Club.

This vagabond genius has bequeathed us a whimsical story of one of his practical jokes upon Goldsmith, in the course of a rural excursion in the vicinity of London. They had dined at an inn on Hampstead Heights, and were descending the hill, when, in passing a cottage, they saw through the open window a party at tea. Goldsmith, who was fatigued, cast a wistful glance at the cheerful tea-table. "How I should like to be of that

party," exclaimed he. "Nothing more easy," replied Glover; "allow me to introduce you." So saying, he entered the house with an air of the most perfect familiarity, though an utter stranger, and was followed by the unsuspecting Goldsmith, who supposed, of course, that he was a friend of the family. The owner of the house rose on the entrance of the strangers. The undaunted Glover shook hands with him in the most cordial manner possible, fixed his eye on one of the company who had a peculiarly happy good-natured physiognomy, muttered something like a recognition, and forthwith launched into an amusing story, invented at the moment, of something which he pretended had occurred upon the road. The host supposed the newcomers were friends of his guests; the guests that they were friends of the host. Glover did not give them time to find out the truth. He followed one droll story with another; brought his powers of mimicry into play, and kept the company in a roar. Tea was offered and accepted; an hour went off in the most sociable manner imaginable, at the end of which Glover bowed himself and his companion out of the house with many facetious last words, leaving the host and his company to compare notes, and to find out what an impudent intrusion they had experienced.

Nothing could exceed the dismay and vexation of Goldsmith when triumphantly told by Glover that it was all a hoax, and that he did not know a single soul in the house. His first impulse was to return instantly and vindicate himself from all participation in the jest; but a few words from his free-and-easy companion dissuaded him. "Doctor," said he, coolly, "we are unknown; you quite as much as I; if you return and tell the story, it will be in the newspapers to-morrow; nay, upon recollection, I remember in one of their offices the face of that squinting fellow who sat in the corner, as if he were treasuring up my stories for future use, and we shall be sure of being exposed; let us therefore keep our own counsel."

This story was frequently afterward told by Glover with rich dramatic effect, repeating and exaggerating the conversation, and mimicking, in ludicrous style, the embarrassment, surprise, and indignation of Goldsmith.

It is a trite saying that a wheel cannot run in two ruts; nor a man keep two opposite sets of intimates. Goldsmith sometimes found his old friends of the "Jolly Pigeon" order turning up rather awkwardly when he was in company with his new aristocratic acquaintances. He gave a whimsical account of the sudden apparition of one of them at his gay apartments in the Temple, who may have been a welcome visitor at his squalid quarters in Green-arbour-court. "How do you think he served me?" said he to a friend. "Why, sir, after staying away two years, he came one evening to my chambers half drunk, as I was taking a glass of wine with Topham Beauclerc and General Oglethorpe; and sitting himself down, with most intolerable assurance inquired after my health and literary pursuits, as if we were upon the most friendly footing. I was at first so much ashamed of ever having known such a fellow, that I stifled my resentment, and drew him into a conversation on such topics as I knew he could talk upon; in which, to do him justice, he acquitted himself very respectably; when all of a sudden, as if recollecting something, he pulled two papers out of his pocket, which he presented to me with great ceremony, saying, 'Here, my dear friend, is a quarter of a pound of tea, and a half a pound of sugar, I have brought you; for though it is not in my power at present to pay you the two guineas you so generously lent me, you, nor any man else, shall ever have it to say that I want gratitude.' This," added Goldsmith, "was too much. I could no longer keep in my feelings, but desired him to turn out of my chambers directly; which he very coolly did, taking up his tea and sugar; and I never saw him afterwards."

## CHAP. XXIV.

Reduced again to book-building—Rural retreat at Shoemakers' Paradise—Death of Henry Goldsmith—Tributes to his memory in the "Deserted Village."

The headless expenses of Goldsmith, as may easily be supposed, soon brought him to the end of his "prize-money," but when his purse gave out he drew upon futurity, obtaining advances from his booksellers and loans from his friends, in the confident hope of soon turning up another trump. The debts which he thus thoughtlessly incurred in consequence of a transient gleam of prosperity embarrassed him for the rest of his life; so that the success of the "Good-natured Man" may be said to have been ruinous to him.

He was soon obliged to resume his old craft of book-building, and set about his "History of Rome," undertaken for Davies.

It was his custom, as we have shown, during the summer time, when pressed by a multiplicity of literary jobs, or urged to the accomplishment of some particular task, to take country lodgings a few miles from town, generally on the Harrow or Edgware road, and bury himself there for weeks and months together. Sometimes he would remain closely occupied in his room; at other times he would stroll out along the lanes and hedge-rows, and, taking out paper and pencil, note down thoughts to be expanded and connected at home. His summer retreat for the present year, 1768, was a little cottage with a garden, pleasantly situated about eight miles from town on the Edgware Road. He took it in conjunction with a Mr. Edmund Botts, a barrister and man of letters, his neighbour in the Temple, having rooms immediately opposite him on the same floor. They had become cordial intimates, and Botts was one of those with whom Goldsmith now and then took the friendly but pernicious system of borrowing.

The cottage which they had hired belonged to a rich shoemaker of Piccadilly, who had embellished his little domain of half an acre with statues and jets, and all the decorations of landscape gardening; in consequence of which Goldsmith gave it the name of "The Shoemaker's Paradise." As his fellow-occupant, Mr. Botts, drove a gig, he sometimes, in an interval of literary labour, accompanied him to town, partook of a social dinner there, and returned with him in the evening. On one occasion, when they had probably lingered too long at the table, they came near breaking their necks on their way homeward by driving against a post on the side-walk, while Botts was proving with legal eloquence that they were in the very middle of the broad Edgware Road.

In the course of this summer, Goldsmith's career of gaiety was suddenly brought to a pause by intelligence of the death of his brother Henry, then but forty-five years of age. He had led a quiet and blameless life amid the scenes of his youth, fulfilling the duties of a village pastor with unaffected piety; conducting the school at Lissoy with a degree of industry and ability that gave it celebrity, and acquitting himself in all the duties of life with undeviating rectitude and the mildest benevolence. How truly Goldsmith loved and venerated him is evident in all his letters and throughout his works, in which his brother continually forms his model for an exemplification of all the most endearing of the Christian virtues; yet his affection at his death was embittered by the fear that he died with some doubt upon his mind of the warmth of his affection. Goldsmith had been urged by his friends in Ireland, since his elevation in the world, to use his influence with the great, which they supposed to be all powerful, in favour of Henry, to obtain for him church preferment. He did exert himself as far as his diffident nature would permit, but without success; we have seen that, in the

case of the Earl of Northumberland, when, as Lord-Lieutenant of Ireland, that nobleman proffered him his patronage, he asked nothing for himself, but only spoke on behalf of his brother. Still some of his friends, ignorant of what he had done, and of how little he was able to do, accused him of negligence. It is not likely, however, that his amiable and estimable brother joined in the accusation.

To the tender and melancholy recollections of his early days, awakened by the death of this loved companion of his childhood, we may attribute some of the most heartfelt passages in the "Deserted Village." Much of that poem, we are told, was composed this summer, in the course of solitary strolls about the green lanes and beautiful rural scenes of the neighbourhood; and thus much of the softness and sweetness of English landscape became blended with the ruder features of Lissoy. It was in these lonely and subdued moments, when tender regret was half mingled with self-upbraiding, that he poured forth that homage of the heart, rendered as it were at the grave of his brother. The picture of the village pastor in this poem, which we have already hinted was taken in part from the character of his father, embodied likewise the recollections of his brother Henry; for the natures of the father and the son seem to be identical. In the following lines, however, Goldsmith evidently contrasted the quiet settled life of his brother, passed at home, in the benevolent exercise of the Christian duties, with his own restless and vagrant career:—

Remote from towns he ran his godly race,  
Nor e'er had changed, nor wish'd to change his place.

To us the whole character seems traced, as it were, in an expiatory spirit; as if, conscious of his own wandering restlessness, he sought to humble himself at the shrine of excellence which he had not been able to practise—

At church, with meek and unaffected grace,  
His looks adorn'd the venerable place:  
Truth from his lips prevail'd with double sway,  
And fools, who came to scoff, remain'd to pray.  
The service past, around the pious man  
With steady zeal each honest rustic ran;  
Even children follow'd with endearing wile,  
And pluck'd his gown to share the good man's smile:  
His ready smile a parent's warmth express'd,  
Their welfare pleas'd him, and their cares distress'd;  
To them his heart, his love, his griefs were given,  
But all his serious thoughts had rest in heaven.

And, as a bird each fond endearment tries  
To tempt its new-fledged offspring to the skies,  
He tried each art, reprov'd each dull delay,  
Allured to brighter worlds, and led the way.

## CHAP. XXV.

Dinner at Bickerstaff's—Hiffernan and his "impecuniosity"—Kenrick's epigram—Johnson's consolation—Goldsmith's toilet—The bloom-coloured coat—New acquaintances—The Hornecks—A touch of poetry and passion—The "Jessamy Bride."

In October, Goldsmith returned to town and resumed his usual haunts. We hear of a dinner given to him by his countryman, Isaac Bickerstaff, author of "Love in a Village," "Lionel and Clarissa," and other successful dramatic pieces. The dinner was to be followed by the reading by Bickerstaff of a new play. Among the guests was one Paul Hiffernan, likewise an Irishman, somewhat idle and intemperate, who lived nobody knew how nor where, sponging wherever he had a chance, and often of course upon Goldsmith, who was ever the vagabond's friend, or rather victim. Hiffernan was something of a physician, and elevated the emptiness of his purse into the dignity of a disease, which he termed *impecuniosity*, and against which he claimed a right to call

for relief from the healthier purses of his friends. He was a scribbler for the newspapers, and latterly a dramatic critic, which had probably gained him an invitation to the dinner and reading. The wine and wassail, however, befogged his senses. Scarce had the author got into the second act of his play, when Hiffernan began to nod, and at length snored outright. Bickerstaff was embarrassed, but continued to read in a more elevated tone. The louder he read the louder Hiffernan snored; until the author came to a pause. "Never mind the brute, Bick., but go on," cried Goldsmith. "He would have served Homer just so, if he were here and reading his own works."

Kenrick, Goldsmith's old enemy, travestied this anecdote in the following lines, pretending that the poet had compared his countryman Bickerstaff to Homer:—

What are your Bretons, Romans, Grecians,  
Compared with thorough-bred Milesians!  
Step into Griffin's shop, he'll tell ye  
Of Goldsmith, Bickerstaff, and Kelly—  
And, take one Irish evidence for t'other,  
E'en Homer's self is but their foster-brother.

Johnson was a rough consolator to a man when wincing under an attack of this kind. "Never mind, sir," said he to Goldsmith, when he saw that he felt the sting. "A man whose business it is to be talked of is much helped by being attacked. Fame, sir, is a shuttlecock; if it be struck only at one end of the room it will soon fall to the ground; to keep it up it must be struck at both ends."

Bickerstaff at the time of which we are speaking was in high vogue, the associate of the first wits of the day; a few years afterwards he was obliged to fly the country to escape the punishment of an infamous crime. Johnson expressed great astonishment at hearing the offence for which he had fled. "Why, sir? said Thrall; 'he had long been a suspected man.' Perhaps there was a knowing look on the part of the eminent brewer, which provoked a somewhat contemptuous reply 'By those who look close to the ground,' said Johnson, 'dirt will sometimes be seen; I hope I see things from a greater distance.'

We have already noticed the improvement, or rather the increased expense, of Goldsmith's wardrobe since his elevation into polite society. "He was fond," said one of his contemporaries, "of exhibiting his muscular little person in the gayest apparel of the day, to which was added a bag-wig and sword." Thus arrayed, he used to figure about in the sunshine in the Temple Gardens, much to his own satisfaction, but to the amusement of his acquaintances.

Boswell, in his memoirs, has rendered one of his suits for ever famous. That worthy, on the 16th of October in this same year, gave a dinner to Johnson, Goldsmith, Reynolds, Garrick, Murphy, Bickerstaff, and Davies. Goldsmith was generally apt to bustle in at the last moment, when the guests were taking their seats at table, but on this occasion he was unusually early. While waiting for some lingerers to arrive, "he strutted about," says Boswell, "bragging of his dress, and I believe was seriously vain of it, for his mind was undoubtedly prone to such impressions. 'Come, come,' said Garrick, 'talk no more of that. You are perhaps the worst—eh, eh!' Goldsmith was eagerly attempting to interrupt him, when Garrick went on, laughing ironically, 'Nay, you will always look like a gentleman; but I am talking of your being well or *ill-dressed*.' 'Well, let me tell you,' said Goldsmith, 'when the tailor brought home my bloom-coloured coat, he said, 'Sir, I have a favour to beg of you; when anybody asks you who made your clothes, be pleased to mention John Filby, at the Harrow, in Water-lane.' 'Why, sir,' cried Johnson, 'that was because he knew the strange colour would attract crowds to gaze at it, and thus they might hear of him, and see how well he could make a coat of so absurd a colour.'

But though Goldsmith might permit this railery on the part of his friends, he was quick to resent any personalities of the kind from strangers. As he was one day walking the Strand in grand array with bag-wig and sword, he excited the merriment of two coxcombs, one of whom called to the other to "look at that fly with a long pin stuck through it." Stung to the quick, Goldsmith's first resort was to caution the passers-by to be on their guard against "that brace of disguised pick-pockets"—his next was to step into the middle of the street, where there was room for action, half-draw his sword, and beckon the joker, who was armed in like manner, to follow him. This was literally a war of wit which the other had not anticipated. He had no inclination to push the joke to such an extreme, but abandoning the ground, sneaked off with his brother wag amid the hootings of the spectators.

This proneness to finery in dress, however, which Boswell and other of Goldsmith's contemporaries, who did not understand the secret plies of his character, attributed to vanity, arose, we are convinced, from a widely different motive. It was from a painful idea of his own personal defects, which had been cruelly stamped upon his mind in his boyhood by the sneers and jeers of his playmates, and had been ground deeper into it by rude speeches made to him in every step of his struggling career, until it had become a constant cause of awkwardness and embarrassment. This he had experienced the more sensibly since his reputation had elevated him into polite society; and he was constantly endeavouring by the aid of dress to acquire that personal acceptability, if we may use the phrase, which nature had denied him. If ever he betrayed a little self-complacency on first turning out in a new suit, it may, perhaps, have been because he felt as if he had achieved a triumph over his ugliness.

There were circumstances, too, about the time of which we are treating, which may have rendered Goldsmith more than usually attentive to his personal appearance. He had recently made the acquaintance of a most agreeable family from Devonshire, which he met at the house of his friend Sir Joshua Reynolds. It consisted of Mrs. Horneck, widow of Captain Kane Horneck; two daughters, seventeen and nineteen years of age, and an only son, Charles, *the Captain in Lace*, as his sisters playfully and somewhat proudly called him, he having lately entered the Guards. The daughters are described as uncommonly beautiful, intelligent, sprightly, and agreeable. Catherine, the eldest, went among her friends by the name of *Little Comedy*—indicative, very probably, of her disposition. She was engaged to William Henry Bunbury, second son of a Suffolk baronet. The hand and heart of her sister Mary were yet unengaged, although she bore the by-name among her friends of the *Jessamy Bride*. This family was prepared, by their intimacy with Reynolds and his sister, to appreciate the merits of Goldsmith. The poet had always been a chosen friend of the eminent painter; and Miss Reynolds, as we have shown, ever since she had heard his poem of "The Traveller" read aloud, had ceased to consider him ugly. The Hornecks were equally capable of forgetting his person in admiring his works. On becoming acquainted with him too, they were delighted with his guileless simplicity, his buoyant good-nature and his innate benevolence, and an enduring intimacy soon sprang up between them. For once poor Goldsmith had met with polite society with which he was perfectly at home, and by which he was fully appreciated; for once he had met with lovely women, to whom his ugly features were not repulsive. A proof of the easy and playful terms in which he was with them remains in a whimsical epistle in verse, of which the following was the occasion. A dinner was to be given to their family by a Dr. Baker, a friend of their mother's, at which Reynolds and Angelica Kauffman were to be present.

The young ladies were eager to have Goldsmith of the party, and their intimacy with Dr. Baker allowing them to take the liberty, they wrote a joint invitation to the poet at the last moment. It came too late, and drew from him the following reply, on the top of which was scrawled, "This is a poem! This is a copy of verses!"

Your mandate I got,	"Little Comedy's" face
You may all go to pot;	And the "Captain in Lace"—
Had your senses been right	Tell each other to rue
You'd have sent before night—	Your Devonshire crew,
So tell Horneck and Nesbitt,	For sending so late
And Baker and his bit,	To one of my state.
And Kauffman beside,	But 'tis Reynolds's way
And the "Jessamy Bride,"	From wisdom to stray,
With the rest of the crew,	And Angelica's whim
The Reynoldses too,	To befool like him:
But, alas! your good worships,	how could they be wiser,
When both have been spoil'd in to-day's "Advertiser!"*	

It has been intimated that the intimacy of poor Goldsmith with the Miss Hornecks, which began in so sprightly a vein, gradually assumed something of a more tender nature, and that he was not insensible to the fascinations of the younger sister. This may account for some of the phenomena which about this time appeared in his wardrobe and toilet. During the first year of his acquaintance with these lovely girls, the tell-tale book of his tailor, Mr. William Filby, displays entries of four or five full suits, besides separate articles of dress. Among the items we find a green half-trimmed frock and breeches, lined with silk; a queen's blue dress suit; a half-dress suit of ratteen, lined with satin; a pair of silk stocking breeches, and another pair of a bloom colour. Alas! poor Goldsmith! how much of this silken finery was dictated, not by vanity, but humble consciousness of thy defects; how much of it was to atone for the uncouthness of thy person, and to win favour in the eyes of the Jessamy Bride!

## CHAP. XXVI.

Goldsmith in the Temple—Judge Day and Grattan—Labour and dissipation—Publication of the "Roman History"—Opinions of it—"History of Animated Nature"—Temple rookery—Anecdotes of a spider.

In the winter of 1768-9, Goldsmith occupied himself at his quarters in the Temple, slowly "building-up" "Roman History." We have pleasant views of him in this learned and half-cloistered retreat of wits and lawyers and legal students, in the reminiscences of Judge Day of the Irish Bench, who in his advanced age delighted to recal the days of his youth, when he was a templar, and to speak of the kindness with which he and his fellow-student Grattan were treated by the poet. "I was just arrived from college," said he "full freighted with academic gleanings, and our author did not disdain to receive from me some opinions and hints towards his Greek and Roman Histories. Being then a young man, I felt much flattered by the notice of so celebrated a person. He took great delight in the conversation of Grattan, whose brilliancy in the morning of life furnished full earnest of the unrivalled splendour which awaited his meridian; and finding us dwelling together in Essex-court, near himself, where

\* The following lines had appeared in that day's "Advertiser," on the portrait of Sir Joshua by Angelica Kauffman:—

"While fair Angelica, with matchless grace,  
Paints Conway's burly form and Stanhope's face,  
Our hearts to beauty willing homage pay—  
We praise, admire, and gaze our souls away.  
But when the likeness she hath done for thee,  
O Reynolds! with astonishment we see,  
Forced to submit, with all our pride we own,  
Such strength, such harmony, excell'd by none,  
And thou art rival'd by thyself alone."

he frequently visited my immortal friend, his warm heart became naturally prepossessed towards the associate of one whom he so much admired."

The judge goes on in his reminiscences to give a picture of Goldsmith's social habits, similar in style to those already furnished. He frequented much the Grecian Coffee-house, then the favourite resort of the Irish and Lancashire Templars. He delighted in collecting his friends around him at evening parties at his chambers, where he entertained them with a cordial and unostentatious hospitality. "Occasionally," adds the judge, "he amused them with his flute, or with whist, neither of which he played well, particularly the latter, but on losing his money he never lost his temper. In a run of bad luck and worse play, he would fling his cards upon the floor and exclaim, 'Bygones George, I ought for ever to renounce thee, fickle, faithless fortune.'"

The judge was aware at the time that all the learned labour of poor Goldsmith upon his "Roman History" was mere hack work to recruit his exhausted finances. "His purse replenished," adds he, "by labours of this kind, the season of relaxation and pleasure took its turn, in attending the theatres, Ranelagh, Vauxhall, and other scenes of gaiety and amusement. Whenever his funds were dissipated—and they fled more rapidly from being the dupe of many artful persons, male and female, who practised upon his benevolence—he returned to his literary labours, and shut himself up from society to provide fresh matter for his bookseller, and fresh supplies for himself."

How completely had the young student discerned the characteristics of poor, genial, generous, drudging, holiday-loving Goldsmith toiling, that he might play; earning his bread by the sweat of his brains, and then throwing it out of the window.

The "Roman History" was published in the middle of May, in two volumes of five hundred pages each. It was brought out without parade or pretension, and was announced as for the use of schools and colleges; but, though a work written for bread, not fame, such is its ease, perspicuity, good sense, and the delightful simplicity of its style, that it was well received by the critics, commanded a prompt and extensive sale, and has ever since remained in the hands of young and old.

Johnson—who, as we have before remarked, rarely praised or dispraised things by halves—broke forth in a warm eulogy of the author and the work, in a conversation with Boswell, to the great astonishment of the latter. "Whether we take Goldsmith," says he, "as a poet, as a comic writer, or as an historian, he stands in the first class." Boswell.—"An historian? My dear sir, you surely will not rank his compilation of 'Roman History' with the works of other historians of this age?" Johnson.—"Why, who are before him?" Boswell.—"Hume, Robertson, Lord Lyttleton." Johnson (his antipathy against the Scotch beginning to rise).—"I have not read Hume; but doubtless Goldsmith's History is better than the verbiage of Robertson, or the foppery of Dalrymple." Boswell.—"Will you not admit the superiority of Robertson, in whose history we find such penetration, such painting?" Johnson.—"Sir, you must consider how that penetration and that painting are employed. It is not history, it is imagination. He who describes what he never saw draws from fancy. Robertson paints minds as Sir Joshua paints faces in a history piece; he imagines an heroic countenance. You must look upon Robertson's work as romance, and try it by that standard. History it is not. Besides, sir, it is the great excellence of a writer to put into his book as much as his book will hold. Goldsmith has done this in his history. Now Robertson might have put twice as much in his book. Robertson is like a man who has packed gold in wool; the wool takes up more room than the gold. No, sir, I always thought Robertson would be

crushed with his own weight—would be buried under his own ornaments. Goldsmith tells you shortly all you want to know; Robertson detains you a great deal too long. No man will read Robertson's cumbrous detail a second time; but Goldsmith's plain narrative will please again and again. I would say to Robertson what an old tutor of a college said to one of his pupils—'Read over your compositions, and, whenever you meet with a passage which you think is particularly fine, strike it out!' Goldsmith's abridgment is better than that of Lucius Florus or Eutropius; and I will venture to say, that if you compare him with Vertot in the same places of the Roman History, you will find that he excels Vertot. Sir, he has the art of compiling, and of saying everything he has to say in a pleasing manner. He is now writing a Natural History, and will make it as entertaining as a Persian tale."

The Natural History to which Johnson alluded was the "History of Animated Nature," which Goldsmith commenced in 1769, under an engagement with Griffin, the bookseller, to complete it as soon as possible in eight volumes, each containing upwards of four hundred pages, in pica; a hundred guineas to be paid to the author on the delivery of each volume in manuscript.

He was induced to engage in this work by the urgent solicitations of the booksellers, who had been struck by the sterling merits and captivating style of an introduction which he wrote to "Brooke's Natural History." It was Goldsmith's intention originally to make a translation of Pliny, with a popular commentary; but the appearance of Buffon's work induced him to change his plan, and to make use of that author for a guide and model.

Cumberland, speaking of this work, observes—"Distress drove Goldsmith upon undertakings neither congenial with his studies nor worthy of his talents. I remember him when, in his chambers in the Temple, he showed me the beginning of his 'Animated Nature'; it was with a sigh, such as genius draws when hard necessity diverts it from its bent to drudge for bread, and talk of birds and beasts, and creeping things, which Pidcock's show-man would have done as well. Poor fellow! he hardly knows an ass from a mule, nor a turkey from a goose, but when he sees it on the table."

Others of Goldsmith's friends entertained similar ideas with respect to his fitness for the task, and they were apt now and then to banter him on the subject, and to amuse themselves with his easy credulity. The custom among the natives of Otaheite of eating dogs being once mentioned in company, Goldsmith observed that a similar custom prevailed in China; that a dog-butcher is as common there as any other butcher; and that, when he walks abroad, all the dogs fall on him. Johnson.—"That is not owing to his killing dogs; sir, I remember a butcher at Lichfield, whom a dog that was in the house where I lived always attacked. It is the smell of carnage which provokes this, let the animals he has killed be what they may." Goldsmith.—"Yes, there is a general abhorrence in animals at the signs of massacre. If you put a tub full of blood into a stable, the horses are likely to go mad." Johnson.—"I doubt that." Goldsmith.—"Nay, sir, it is a fact well authenticated." Thrale.—"You had better prove it before you put it into your book on Natural History. You may do it in my stable if you will." Johnson.—"Nay, sir, I would not have him prove it. If he is content to take his information from others, he may get through his book with little trouble, and without much endangering his reputation. But if he makes experiments for so comprehensive a book as his, there would be no end to them; his erroneous assertions would fall then upon himself; and he might be blamed for not having made experiments as to every particular."

Johnson's original prediction, however, with respect to this work, that Goldsmith would make it as enter-

taining as a Persian tale, was verified; and though much of it was borrowed from Buffon, and but little of it written from his own observation; though it was by no means profound, and was chargeable with many errors, yet the charms of his style and the play of his happy disposition throughout have continued to render it far more popular and readable than many works on the subject of much greater scope and science. Cumberland was mistaken, however, in his notion of Goldsmith's ignorance and lack of observation as to the characteristics of animals. On the contrary, he was a minute and shrewd observer of them; but he observed them with the eye of a poet and a moralist as well as a naturalist. We quote two passages from his works illustrative of this fact, and we do so the more readily because they are in a manner a part of his history, and give us another peep into his private life in the Temple, of his mode of occupying himself in his lonely and apparently idle moments, and of another class of acquaintances which he made there.

Speaking in his "Animated Nature" of the habitudes of rooks, "I have often amused myself," says he, "with observing their plans of policy from my window in the Temple, that looks upon a grove, where they have made a colony in the midst of a city. At the commencement of spring the rookery, which, during the continuance of winter, seemed to have been deserted, or only guarded by about five or six, like old soldiers in a garrison, now begins to be once more frequented; and in a short time all the bustle and hurry of business will be fairly commenced."

The other passage which we take the liberty to quote at some length is from an admirable paper in the "Bee," and relates to the house-spider.

"Of all the solitary insects I have ever remarked, the spider is the most sagacious, and its motions to me, who have attentively considered them, seem almost to exceed belief. \* \* \* I perceived, about four years ago, a large spider in one corner of my room making its web; and, though the maid frequently levelled her broom against the labours of the little animal, I had the good fortune then to prevent its destruction, and I may say it more than paid me by the entertainment it afforded.

"In three days the web was, with incredible diligence, completed; nor could I avoid thinking that the insect seemed to exult in its new abode. It frequently traversed it round, examined the strength of every part of it, retired into its hole, and came out very frequently. The first enemy, however, it had to encounter was another and a much larger spider, which having no web of its own, and having probably exhausted all its stock in former labours of this kind, came to invade the property of its neighbour. Soon, then, a terrible encounter ensued, in which the invader seemed to have the victory, and the laborious spider was obliged to take refuge in its hole. Upon this I perceived the victor using every art to draw the enemy from its stronghold. He seemed to go off, but quickly returned; and when he found all arts in vain, began to demolish the new web without mercy. This brought on another battle, and, contrary to my expectations, the laborious spider became conqueror, and fairly killed his antagonist.

"Now, then, in peaceable possession of what was justly its own, it waited three days with the utmost impatience, repairing the breaches of its web, and taking no sustenance that I could perceive. At last, however, a large blue fly fell into the snare, and struggled hard to get loose. The spider gave it leave to entangle itself as much as possible, but seemed to be too strong for the cobweb. I must own I was greatly surprised when I saw the spider immediately sally out, and in less than a minute weave a new net round its captive, by which the motion of its wings was stopped; and, when it was fairly hampered in this manner, it was seized and dragged into the hole.

"In this manner it lived in a precarious state; and nature seemed to have fitted it for such a life, for upon a single fly it subsisted for more than a week. I once put a wasp into the net; but when the spider came out in order to seize it as usual, upon perceiving what kind of an enemy it had to deal with it instantly broke all the bands that held it fast, and contributed all that lay in its power to disengage so formidable an antagonist. When the wasp was set at liberty, I expected the spider would have set about repairing the breaches that were made in its net; but those, it seems, were irreparable: wherefore the cobweb was now entirely forsaken, and a new one begun, which was completed in the usual time.

"I had now a mind to try how many cobwebs a single spider could furnish; wherefore I destroyed this, and the insect set about another. When I destroyed the other also, its whole stock seemed exhausted, and it could spin no more. The arts it made use of to support itself, now deprived of its great means of subsistence, were indeed surprising. I have seen it roll up its legs like a ball, and lie motionless for hours together, but cautiously watching all the time: when a fly happened to approach sufficiently near, it would dart out all at once, and often seize its prey.

"Of this life, however, it soon began to grow weary, and resolved to invade the possession of some other spider, since it could not make a web of its own. It formed an attack upon a neighbouring fortification with great vigour, and at first was as vigorously repulsed. Not daunted, however, with one defeat, in this manner it continued to lay siege to another's web for three days, and at length, having killed the defendant, actually took possession. When smaller flies happen to fall into the snare, the spider does not sally out at once, but very patiently waits till it is sure of them; for, upon his immediately approaching, the terror of his appearance might give the captive strength sufficient to get loose; the manner, then, is to wait patiently till, by ineffectual and impotent struggles, the captive has wasted all its strength, and then he becomes a certain and easy conquest.

"The insect I am now describing lived three years, every year it changed its skin and got a new set of legs. I have sometimes plucked off a leg, which grew again in two or three days. At first it dreaded my approach to its web, but at last it became so familiar as to take a fly out of my hand; and, upon touching any part of the web, would immediately leave its hole, prepared either for a defence or an attack."

## CHAP. XXVII.

Honours at the Royal Academy—Letter to his brother Maurice—Family fortunes—Jane Contarine and the miniature—Portraits and engravings—School associations—Johnson and Goldsmith in Westminster Abbey.

The latter part of the year 1768 had been made memorable in the world of taste by the institution of the Royal Academy of Arts, under the patronage of the King, and the direction of forty of the most distinguished artists. Reynolds, who had been mainly instrumental in founding it, had been unanimously elected president, and had thereupon received the honour of knighthood.\* Johnson was so delighted with his friend's elevation, that he broke through a rule of total abstinence with respect to wine, which he had maintained for several

\* We must apologise for the anachronism we have permitted ourselves in the course of this memoir, in speaking of Reynolds as "Sir Joshua," when treating of circumstances which occurred prior to his being dubbed; but it is so customary to speak of him by that title, that we found it difficult to dispense with it.

years, and drank bumpers on the occasion. Sir Joshua eagerly sought to associate his old and valued friends with him in his new honours, and it is supposed to be through his suggestions that, on the first establishment of professorships, which took place in December, 1769, Johnson was nominated to that of Ancient Literature, and Goldsmith to that of History. They were mere honorary titles, without emolument, but gave distinction, from the noble institution to which they appertained. They also gave the possessors honourable places at the annual banquet, at which were assembled many of the most distinguished persons of rank and talent, all proud to be classed among the patrons of the arts.

The following letter of Goldsmith to his brother alludes to the foregoing appointment, and to a small legacy bequeathed to him by his uncle Contarine:—

*"To Mr. Maurice Goldsmith, at James Lawder's, Esq., at Kilmore, near Carrick-on-Shannon.*

*"January, 1770.*

"DEAR BROTHER,—I should have answered your letter sooner, but, in truth, I am fond of thinking of the necessities of those I love, when it is so very little in my power to help them. I am sorry to find you are every way unprovided for; and what adds to my uneasiness is, that I have received a letter from my sister Johnson, by which I learn that she is pretty much in the same circumstances. As to myself, I believe I think I could get both you and my poor brother-in-law something like that which you desire, but I am determined never to ask for little things, nor exhaust any little interest I may have, until I can serve you, him, and myself more effectually. As yet no opportunity has offered; but I believe you are pretty well convinced that I will not be remiss when it arrives.

"The king has lately been pleased to make me Professor of Ancient History in the Royal Academy of Painting, which he has just established, but there is no salary annexed; and I took it rather as a compliment to the institution than any benefit to myself. Honours to one in my situation are something like ruffles to one that wants a shirt.

"You tell me that there are fourteen or fifteen pounds left me in the hands of my cousin Lawder, and you ask me what I would have done with them. My dear brother, I would by no means give any directions to my dear worthy relations at Kilmore how to dispose of money which is, properly speaking, more theirs than mine. All that I can say is, that I entirely, and this letter will serve to witness, give up my right and title to it; and I am sure they will dispose of it to the best advantage. To them I entirely leave it; whether they or you may think the whole necessary to fit you out, or whether our poor sister Johnson may not want the half, I leave entirely to their and your discretion. The kindness of that good couple to our shattered family demands our sincerest gratitude; and, though they have almost forgotten me, yet, if good things at last arrive, I hope one day to return and increase their good-humour by adding to my own.

"I have sent my cousin Jenny a miniature portrait of myself, as I believe it is the most acceptable present I can offer. I have ordered it to be left for her at George Faulkener's folded in a letter. The face, you well know, is ugly enough, but it is finely painted. I will shortly also send my friends over the Shannon some mezzotinto prints of myself, and some more of my friends here, such as Burke, Johnson, Reynolds, and Colman. I believe I have written a hundred letters to different friends in your country, and never received an answer to any of them. I do not know how to account for this, or why they are unwilling to keep up for me those regards which I must ever retain for them.

"If, then, you have a mind to oblige me, you will write often, whether I answer you or not. Let me par-

ticularly have the news of our family and old acquaintances. For instance, you may begin by telling me about the family where you reside, how they spend their time, and whether they ever make mention of me. Tell me about my mother, my brother Hodson and his son, my brother Harry's son and daughter, my Sister Johnson, the family of Ballyoughter, what is become of them, where they live, and how they do. You talked of being my only brother: I don't understand you. Where is Charles? A sheet of paper occasionally filled with the news of this kind would make me very happy, and would keep you nearer my mind. As it is, my dear brother, believe me to be,

"Yours, most affectionately,

"OLIVER GOLDSMITH."

By this letter we find the Goldsmiths the same shifting, shiftless race as formerly—a "shattered family," scrambling on each other's back as soon as any rise above the surface. Maurice is "every way unprovided for;" living upon cousin Jane and her husband; and, perhaps, amusing himself by hunting otter in the river Lunny. Sister Johnson and her husband are as poor off as Maurice, with, perhaps, no one at hand to quarter themselves upon; as to the rest, "what is become of them; where do they live; how do they do; what is become of Charles?" What forlorn, hap-hazard life is implied by these questions! Can we wonder that, with all the love for his native place which is shown throughout Goldsmith's writings, he had not the heart to return there? Yet his affections are still there. He wishes to know whether the Lawders (which means his cousin Jane, his early Valentine) ever make mention of him; he sends Jane his miniature; he believes "it is the most acceptable present he can offer;" he evidently, therefore, does not believe she has almost forgotten him, although he intimates that he does: in his memory she is still Jane Contarine, as he last saw her, when he accompanied her harpsichord with his flute. Absence, like death, sets a seal on the image of those we have loved; we cannot realise the intervening changes which time may have effected.

As to the rest of Goldsmith's relatives, he abandons his legacy of fifteen pounds to be shared among them. It is all he has to give. His heedless improvidence is eating up the pay of the booksellers in advance. With all his literary success, he has neither money nor influence; but he has empty fame, and he is ready to participate with them; he is honorary professor, without pay; his portrait is to be engraved in mezzotint, in company with those of his friends, Burke, Reynolds, Johnson, Colman, and others, and he will send prints of them to his friends over the Shannon, though they may not have a house to hang them up in. What a motley letter! How indicative of the motley character of the writer! By-the-by, the publication of a splendid mezzotinto engraving of his likeness by Reynolds was a great matter of glorification to Goldsmith, especially as it appeared in such illustrious company. As he was one day walking the streets in a state of high elation, from having just seen it figuring in the print-shop windows, he met a young gentleman with a newly-married wife hanging on his arm, whom he immediately recognised for Master Bishop, one of the boys he had petted and treated with sweetmeats when an humble usher at Milner's school. The kindly feelings of old times revived, and he accosted him with cordial familiarity, though the youth may have found some difficulty in recognising in the personage, arrayed, perhaps, in garments of Tyrian dye, the dingy pedagogue of the Milners. "Come, my boy," cried Goldsmith, as if still speaking to a school-boy, "Come, Sam, I am delighted to see you. I must treat you to something—what shall it be? Will you have some apples?" glancing at an old woman's stall; then recollecting the print-shop window, "Sam," said he, "have you seen my picture, by Sir Joshua Reynolds? Have

you seen it, Sam? Have you got an engraving?" Bishop was caught; he equivocated; he had not yet bought it; but he was furnishing his house, and had fixed upon a place where it was to be hung. "Ah, Sam!" rejoined Goldsmith reproachfully, "if your picture had been published, I should not have waited an hour without having it."

After all, it was honest pride, not vanity, in Goldsmith, that was gratified at seeing his portrait deemed worthy of being perpetuated by the classic pencil of Reynolds, and "hung up in history" beside that of his revered friend Johnson. Even the great moralist himself was not insensible to a feeling of this kind. Walking one day with Goldsmith, in Westminster Abbey, among the tombs of monarchs, warriors, and statesmen, they came to the sculptured mementoes of literary worthies in poet's-corner. Casting his eyes round upon these memorials of genius, Johnson muttered in a low tone to his companion—

*Forsit an nostrum nomen miscabitur istis.*

Goldsmith treasured up the intimated hope, and shortly afterwards, as they were passing by Temple-bar, where the heads of the Jacobite rebels, executed for treason, were mouldering aloft on spikes, pointed up to the grizzly mementoes, and echoed the intimation—

*Forsit an nostrum nomen miscabitur istis.*

## CHAP. XXVIII.

Publication of the "Deserted Village"—Notices and illustrations of it.

Several years had now elapsed since the publication of "The Traveller," and much wonder was expressed that the great success of that poem had not incited the author to further poetic attempts. On being questioned at the annual dinner of the Royal Academy by the Earl of Lisburn, why he neglected the muses to compile histories and write novels, "My Lord," replied he, "by courting the muses I shall starve; but by my other labours I eat, drink, have good clothes, and can enjoy the luxuries of life." So, also, on being asked by a poor writer what was the most profitable mode of exercising the pen, "My dear fellow," replied he, good humouredly, "pay no regard to the draggle-tailed muses; for my part I have found productions in prose much more sought after and better paid for."

Still, however, as we have heretofore shown, he found sweet moments of dalliance to steal away from his prosaic toils, and court the muse among the green lanes and hedge-rows in the rural environs of London, and on the 26th of May, 1770, he was enabled to bring his "Deserted Village" before the public.

The popularity of "The Traveller" had prepared the way for this poem, and its sale was instantaneous and immense. The first edition was immediately exhausted; in a few days more a second was issued; in a few days more a third, and by the 16th of August the fifth edition was hurried through the press. As is the case with popular writers, he had become his own rival, and critics were inclined to give the preference to his first poem; but with the public at large, we believe the "Deserted Village" has ever been the greatest favourite. Previous to its publication, the bookseller gave him in advance a note for the price agreed upon, one hundred guineas. As the latter was returning home he met a friend, to whom he mentioned the circumstance, and who, apparently judging of the poetry by quantity rather than quality, observed that it was a great sum for so small a poem. "In truth," said Goldsmith, "I think so too; it is much more than the honest man can afford or the piece is worth. I have not been easy since I received it." In fact, he actually returned the note to

the bookseller, and left it to him to graduate the payment according to the success of the work. The bookseller, as may well be supposed, soon repaid him in full, with many acknowledgments of his disinterestedness. This anecdote has been called in question, we know not on what grounds; we see nothing in it incompatible with the character of Goldsmith, who was very impulsive, and prone to acts of inconsiderate generosity.

As we do not pretend, in this summary memoir, to go into a criticism or analysis of any of Goldsmith's writings, we shall not dwell upon the peculiar merits of this poem; we cannot help noticing, however, how truly it is a mirror of the author's heart, and of all fond pictures of early friends and early life for ever present there. It seems to us as if the very last accounts received from home of his "shattered family," and the desolation that seemed to have settled upon the haunts of his childhood, had cut to the roots one feebly-cherished hope, and produced the following exquisitely tender and mournful lines:—

In all my wand'rings round this world of care,  
In all my griefs—and God has giv'n my share—  
I still had hopes my latest hours to crown,  
Amid these humble bowers to lay me down;  
To husband out life's taper at the close,  
And keep the flame from wasting by repose:  
I still had hopes, for pride attends us still,  
Amid the swains to show my book-learn'd skill,  
Around my fire an evening group to draw,  
And tell of all I felt and all I saw;  
And as a hare, whom hounds and horns pursue,  
Pants to the place from which at first she flew,  
I still had hopes, my long vexations past,  
Here to return—and die at home at last.

How touchingly expressive are the succeeding lines, wrung from a heart which all the trials and temptations and buffetings of the world could not render worldly! which, amid a thousand follies and errors of the head, still retained its childlike innocence; and which, doomed to struggle on to the last amidst the din and turmoil of the metropolis, had ever been cheating itself with a dream of rural quiet and seclusion:—

Oh bless'd retirement! friend to life's decline,  
Retreats from care, that never must be mine;  
How blest is he who crowns, in shades like these,  
A youth of labour with an age of ease;  
Who quits a world where strong temptations try,  
And, since 'tis hard to combat, learns to fly!  
For him no wretches, born to work and weep,  
Explore the mine or tempt the dangerous deep:  
Nor surly porter stands, in guilty state,  
To spurn imploring famine from the gate;  
But on he moves to meet his latter end,  
Angels around befriending Virtue's friend;  
Sinks to the grave with unperceived decay,  
While resignation gently slopes the way;  
And all his prospects brightening to the last,  
His heaven commences ere the world be past.

NOTE.—The following article, which appeared in a London periodical, shows the effect of Goldsmith's poem in renovating the fortunes of Lissoy:—

"About three miles from Ballymahon, a very central town in the sister kingdom, is the mansion and village of Auburn, so called by their present possessor, Captain Hogan. Through the taste and improvement of this gentleman, it is now a beautiful spot, although fifteen years since it presented a very bare and unpoetical aspect. This, however, was owing to a cause which serves strongly to corroborate the assertion, that Goldsmith had this scene in view when he wrote his poem of 'The Deserted Village.' The then possessor, General Napier, turned all his tenants out of their farms, that he might enclose them in his own private domain. Littleton, the mansion of the general, stands not far off, a complete emblem of the desolating spirit lamented by the poet, dilapidated, and converted into a barrack.

"The chief object of attraction is Lissoy, once the parsonage-house of Henry Goldsmith, that brother to

whom the poet dedicated his 'Traveller,' and who is represented as the village-pastor,

Passing rich with forty pounds a year.

"When I was in the country the lower chambers were inhabited by pigs and sheep, and the drawing-room by oats. Captain Hogan, however, has, I believe, got it since into his possession, and has, of course, improved its condition.

"Though at first strongly inclined to dispute the identity of Auburn, Lissoy House overcame my scruples. As I clambered over the rotten gate, and crossed the grass-grown lawn or court, the tide of association became too strong for casuistry: here the poet dwelt and wrote, and here his thoughts fondly recurred when composing his 'Traveller' in a foreign land. Yonder was the decent church, that literally 'topped the neighbouring hill.' Before me lay the little hill of Knockree, on which he declares, in one of his letters, he had rather sit with a book in hand than mingle in the proudest assemblies. And, above all, startlingly true, beneath my feet was

Yonder copse, where once the garden smiled,  
And still where many a garden-flower grows wild.

"A painting from the life could not be more exact. 'The stubborn currant-bush' lifts its head above the rank grass, and the proud hollyoak flaunts where its sisters of the flower-knot are no more.

"In the middle of the village stands the old 'hawthorn-tree,' built up with masonry to distinguish and preserve it; it is old and stunted, and suffers much from the depredations of post-chaise travellers, who generally stop to procure a twig. Opposite to it is the village alehouse, over the door of which swings 'The Three Jolly Pigeons.' Within, everything is arranged according to the letter:—

The whitewash'd wall, the nicely-sanded floor,  
The varnish'd clock that click'd behind the door:  
The chest, contrived a double debt to pay—  
A bed by night, a chest of drawers by day;  
The pictures placed for ornament and use,  
The twelve good rules, the royal game of goose.

"Captain Hogan, I have heard, found great difficulty in obtaining 'the twelve good rules,' but at length purchased them at some London bookstall to adorn the whitewashed parlour of 'The Three Pigeons.' However laudable this may be, nothing shook my faith in the reality of Auburn so much as this exactness, which had the disagreeable air of being got up for the occasion. The last object of pilgrimage is the quondam habitation of the schoolmaster—

There, in his noisy mansion, skill'd to rule.  
It is surrounded with fragrant proofs of identity in

The blossom'd furze, unprofitably gay.

"There is to be seen the chair of the poet, which fell into the hands of its present possessors at the wreck of the parsonage-house; they have frequently refused large offers of purchase; but more, I dare say, for the sake of drawing contributions from the curious than from any reverence for the bard. The chair is of oak, with back and seat of cane, which precluded all hopes of a secret drawer, like that lately discovered in Gay's. There is no fear of its being worn out by the devout earnestness of sitters—as the cocks and hens have usurped undisputed possession of it, and protest most clamorously against all attempts to get it cleansed, or to seat one's self.

"The controversy concerning the identity of this Auburn was formerly a standing theme of discussion among the learned of the neighbourhood; but, since the *pros* and *cons* have been all ascertained, the argument has died away. Its abettors plead the singular agreement between the local history of the place and the scenery of the poem, and the exactness with which the scenery of the one answers to the description of the other. To this is opposed the mention of the nightingale—

And fill'd each pause the nightingale had made—

there being no such bird in the island. The objection is slighted, on the other hand, by considering the passage as a mere poetical licence. 'Besides,' say they, 'the robin is the Irish nightingale.' And if it be hinted how unlikely it was that Goldsmith should have laid the scene in a place from which he was, and had been, so long absent, the rejoinder is always, 'Pray, sir, was Milton in hell when he built Pandemonium?'

"The line is naturally drawn between; there can be no doubt that the poet intended England by

The land to hast'ning ills a prey,  
Where wealth accumulates and men decay.

But it is very natural to suppose that, at the same time, his imagination had in view the scenes of his youth, which give such strong features of resemblance to the picture."

Best, an Irish clergyman, told Davis, the traveller in America, that the hawthorn bush, mentioned in the poem, was still remarkably large. "I was riding once," said he, "with Brady, titular Bishop of Ardagh, when he observed to me, 'Ma foy, Best, this huge overgrown bush is mightily in the way. I will order it to be cut down.'—'What, sir!' replied I, 'cut down the bush that supplies so beautiful an image in 'The Deserted Village?'—'Ma foy!' exclaimed the bishop, 'is that the hawthorn-bush? Then let it be sacred from the edge of the axe, and evil be to him that should cut off a branch.'"—The hawthorn-bush, however, has long since been cut up, root and branch, in furnishing relics to literary pilgrims.

## CHAP. XXIX.

The Poet among the ladies—Description of his person and manners—Expedition to Paris with the Horneck family—The traveller of twenty and the traveller of forty—Hickey, the special attorney—An unlucky exploit.

"The Deserted Village" had shed an additional poetic grace round the homely person of the author; he was becoming more and more acceptable in ladies' eyes, and finding himself more and more at ease in their society; at least in the society of those whom he met in the Reynolds circle, among whom he particularly affected the beautiful family of the Hornecks.

But let us see what were really the looks and manners of Goldsmith about this time, and what right he had to aspire to ladies' smiles; and, in so doing, let us not take the sketches of Boswell and his compeers, who had a propensity to represent him in caricature; but let us take the apparently truthful and discriminating picture of him as he appeared to Judge Day, when the latter was a student in the Temple.

"In person," says the judge, "he was short; about five feet five or six inches; strong, but not heavy made; rather fair in complexion, with brown hair; such, at least, as could be distinguished from his wig. His features were plain but not repulsive—certainly not so when lighted up by conversation. His manners were simple, natural, and perhaps on the whole, we may say, not polished—at least, without the refinement and good-breeding which the exquisite polish of his compositions would lead us to expect. He was always cheerful and animated, often, indeed, boisterous in his mirth; entered with spirit into convivial society; contributed largely to its enjoyments by solidity of information, and the naïveté and originality of his character; talked often without premeditation, and laughed loudly without restraint."

This, it will be recollected, represents him as he appeared to a young Templar, who probably saw him only in Temple coffee-houses, at students' quarters, or at the jovial supper-parties given at the poet's own chambers; here, of course, his mind was in its rough dress; his

laugh may have been loud, and his mirth boisterous; but we trust all these matters became softened and modified when he found himself in polite drawing-rooms and in female society.

But what say the ladies themselves of him? and here, fortunately, we have another sketch of him, as he appeared at the time to one of the Horneck circle—in fact, we believe, to the Jessamy Bride herself. After admitting, apparently with some reluctance, that “he was a very plain man,” she goes on to say, “but had he been much more so, it was impossible not to love and respect his goodness of heart, which broke out on every occasion. His benevolence was unquestionable, and his countenance bore every trace of it: no one that knew him intimately could avoid admiring and loving his good qualities.” When to all this we add the idea of intellectual delicacy and refinement associated with him by his poetry, and the newly-plucked brows that were flourishing round his brow, we cannot be surprised that fine and fashionable ladies should be proud of his attentions, and that even a young beauty should not be altogether displeased with the thoughts of having a man of his genius in her chains.

We are led to indulge some notions of the kind from finding him in the month of July, but a few weeks after the publication of the “Deserted Village,” setting off on a six weeks’ excursion to Paris, in company with Mrs. Horneck and her two beautiful daughters. A day or two before his departure, we find another new gala suit charged to him on the books of Mr. William Filby. Were the bright eyes of the Jessamy Bride responsible for this additional extravagance of wardrobe? Goldsmith had recently been editing the works of Parnell; had he taken courage from the example of Edwin, in the Fairy tale?—

Yet spite of all that nature did  
To make his uncouth form forbid,  
This creature dared to love.  
He felt the force of Edith’s eyes,  
Nor wanted hope to gain the prize  
Could ladies look within—

All this we throw out as mere hints and surmises, leaving it to our readers to draw their own conclusions. It will be found, however, that the poet was subject to shrewd bantering among his contemporaries about the beautiful Mary Horneck, and that he was extremely sensitive on the subject.

It was in the month of June that he set out for Paris with his fair companions, and the following letter was written by him to Sir Joshua Reynolds, soon after the party landed at Calais:—

“MY DEAR FRIEND,—We had a very quick passage from Dover to Calais, which we performed in three hours and twenty minutes, all of us extremely sea-sick, which must necessarily have happened, as my machine to prevent sea-sickness was not completed. We were glad to leave Dover, because we hated to be imposed upon; so were in high spirits at coming to Calais, where we were told that a little money would go a great way.

“Upon landing, with two little trunks, which were all we carried with us, we were surprised to see fourteen or fifteen fellows all running down to the ship to lay their hands upon them; four got under each trunk, the rest surrounded and held the haps; and in this manner our little baggage was conducted with a kind of funeral solemnity, till it was safely lodged at the custom-house. We were well enough pleased with the people’s civility till they came to be paid; every creature that had the happiness of but touching our trunks with their finger expected sixpence; and they had so pretty and civil a manner of demanding it, that there was no refusing them.

“When we had done with the porters, we had next to speak with the custom-house officers, who had their pretty civil way too. We were directed to the Hotel d’Angleterre, where a valet-de-place came to offer his

service, and spoke to me ten minutes before I once found out that he was speaking English. We had no occasion for his services, so we gave him a little money because he spoke English, and because he wanted it. I cannot help mentioning another circumstance: I bought a new riband for my wig at Canterbury, and the barber at Calais broke it, in order to gain sixpence by buying me a new one.”

An incident which occurred in the course of this tour has been tortured by that literary magpie, Boswell, into a proof of Goldsmith’s absurd jealousy of any admiration shown to others in his presence. While stopping at an hotel in Lisle, they were drawn to the windows by a military parade in front. The extreme beauty of the Miss Hornecks immediately attracted the attention of the officers, who broke forth with enthusiastic speeches and compliments intended for their ears. Goldsmith was amused for awhile, but at length affected impatience at this exclusive admiration of his beautiful companions, and exclaimed with mock severity of aspect, “Elsewhere I also would have my admirers.”

It is difficult to conceive the obtuseness of intellect necessary to misconstrue so obvious a piece of mock petulance and dry humour into an instance of mortified vanity and jealous self-conceit.

Goldsmith jealous of the admiration of a group of gay officers for the charms of two beautiful young women! This even out-Boswells Boswell; yet this is but one of several similar absurdities, evidently misconceptions of Goldsmith’s peculiar vein of humour, by which the charge of envious jealousy has been attempted to be fixed upon him. In the present instance it was contradicted by one of the ladies herself, who was annoyed that it had been advanced against him. “I am sure,” said she, “from the peculiar manner of his humour and assumed frown of countenance what was often uttered in jest was mistaken by those who did not know him for earnest.” No one was more prone to err on this point than Boswell. He had a tolerable perception of wit, but none of humour.

The following letter to Sir Joshua Reynolds was subsequently written:—

“To Sir Joshua Reynolds.

“Paris, July 22, 1770.  
“MY DEAR FRIEND,—I began a long letter to you from Lisle, giving a description of that we had done and seen; but finding it very dull, and knowing that you would show it again, I threw it aside and it was lost. You see by the top of this letter that we are at Paris, and (as I have often heard you say) we have brought our own amusement with us, for the ladies do not seem to be very fond of what we have yet seen.

“With regard to myself, I find that travelling at twenty and forty are very different things. I set out with all my confirmed habits about me, and can find nothing on the continent so good as when I formerly left it. One of our chief amusements here is scolding at everything we meet with, and praising everything and every person we left at home. You may judge, therefore, whether your name is not frequently bandied at table among us. To tell you the truth, I never thought I could regret your absence so much as our various mortifications on the road have often taught me to do. I could tell you of disasters and adventures without number; of our lying in barns, and of my being half-poisoned with a dish of green peas; of our quarrelling with postillions, and being cheated by our landladies; but I reserve all this for a happy hour, which I expect to share with you upon my return.

“I have little to tell you more but that we are at present all well, and expect returning when we have stayed out one month, which I did not care if it were over this very day. I long to hear from you all, how you yourself do, how Johnson, Brooke, Dyer, Chamier, Colman, and every one of the club do. I wish I could send you

some amusement in this letter, but I protest I am so stupified by the air of this country (for I am sure it cannot be natural) that I have not a word to say. I have been thinking of the plot of a comedy, which shall be entitled "A Journey to Paris," in which a family shall be introduced with a full intention of going to France to save money. You know there is not a place in the world more promising for that purpose. As for the meat of this country, I can scarce eat it; and, though we pay two good shillings a-head for our dinner, I find it all so tough that I have spent less time with my knife than my picktooth. I said this as a good thing at the table, but it was not understood. I believe it to be a good thing.

"As for our intended journey to Devonshire, I find it out of my power to perform it; for, as soon as I arrive at Dover, I intend to let the ladies go on, and I will take a country lodging somewhere near that place in order to do some business. I have so outrun the constable that I must mortify a little to bring it up again. For God's sake, the night you receive this, take your pen in your hand and tell me something about yourself and myself, if you know anything that has happened. About Miss Reynolds, about Mr. Bickerstaff, my nephew, or anybody that you regard. I beg you will send to Griffin, the bookseller, to know if there be any letters left for me, and be so good as to send them to me in Paris. They may, perhaps, be left for me at the Porter's Lodge, opposite the pump in Temple Lane. The same messenger will do. I expect one from Lord Clare from Ireland. As for the others, I am not much uneasy about.

"Is there anything I can do for you at Paris? I wish you would tell me. The whole of my own purchases here is one silk coat, which I have put on, and which makes me look like a fool. But no more of that. I find that Colman has gained his lawsuit. I am glad of it. I suppose you often meet. I will soon be among you, better pleased with my situation at home than ever I was before. And yet I must say, that if anything could make France pleasant, the very good women with whom I am at present would certainly do it. I could say more about that, but I intend showing them the letter before I send it away. What signifies teasing you longer with moral observations, when the business of my writing is over? I have one thing only more to say, and of that I think every hour of the day, namely, that I am your most sincere and most affectionate friend,

"OLIVER GOLDSMITH.

"Direct for me at the Hotel de Danemarc,  
Rue Jacob, Faubourg St. Germain."

A word of comment on this letter. Travelling is, indeed, a very different thing with Goldsmith the poor student at twenty, and Goldsmith the poet and professor at forty. At twenty, though obliged to trudge on foot from town to town and country to country, paying for a supper and a bed by a tune on the flute, everything pleased, everything was good; a truckle-bed in a garret was a couch of down, and the homely fare of the peasant a feast fit for an epicure. Now, at forty, when he posts through the country in a carriage, with fair ladies by his side, everything goes wrong; he has to quarrel with postillions, he is cheated by landladies, the hotels are barns, the meat is too tough to be eaten, and he is half-poisoned by green-peas! A line in his letter explains the secret; "the ladies do not seem very fond of what we have yet seen." "One of our chief amusements is scolding at everything we meet with, and praising everything and every person we left at home!" The true English travelling amusement. Poor Goldsmith! he has "all his *confirmed habits* about him;" that is to say, he has recently risen into high life, and acquired high bred notions; he must be fastidious like his fellow-travellers; he dare not be pleased with what pleased the vulgar tastes of his youth. He is unconsciously illus-

trating the trait so humorously satirised by him in Bill Tibbs the shabby beau, who can find "no such dressing as he had at Lord Crump's or Lady Crimp's;" whose very senses have grown genteel, and who no longer "smacks at wretched wine or praises detestable custard." A lurking thorn, too, is worrying him throughout this tour; he has "outrun the constable;" that is to say, his expenses have outrun his means, and he will have to make up for this butterfly flight by toiling like a grub on his return.

Another circumstance contributes to mar the pleasure he had promised himself in this excursion. At Paris, the party is unexpectedly joined by a Mr. Hickey, a bustling attorney, who is well acquainted with that metropolis and its environs, and insists on playing the eicerone on all occasions. He and Goldsmith do not relish each other, and they have several petty altercations. The lawyer is too much a man of business and method for the careless poet, and is disposed to manage everything. He has perceived Goldsmith's whimsical peculiarities without properly appreciating his merits, and is prone to indulge in broad bantering and railery at his expense—particularly irksome if indulged in presence of the ladies. He makes himself merry on his return to England by giving the following anecdote as illustrative of Goldsmith's vanity:—

"Being with a party at Versailles, viewing the water-works, a question arose among the gentlemen present whether the distance from whence they stood to one of the little islands was within the compass of a leap. Goldsmith maintained the affirmative; but, being bantered on the subject, and remembering his former prowess as a youth, attempted the leap, but, falling short, descended into the water, to the great amusement of the company."

Was the Jessamy Bride a witness to this unlucky exploit?

This same Hickey is the one of whom Goldsmith, some time subsequently, gave a good-humoured sketch, in his poem of "The Retaliation."

Here Hickey reclines, a most blunt, pleasant creature,  
And slander itself must allow him good nature;  
He cherish'd his friend and he relish'd a bumper,  
Yet one fault he had, and that one a thumper.  
Perhaps you may ask if the man was a miser?  
I answer No, no—for he always was wiser;  
Too courteous, perhaps, or obligingly flat?  
His very worst foe can't accuse him of that;  
Perhaps he confided in men as they go,  
And so was too foolishly honest? Ah, no!  
Then what was his failing? Come, tell it, and burn ye—  
He was, could he help it? a special attorney.

One of the few remarks extant made by Goldsmith during his tour is the following, of whimsical import, in his "Animated Nature."

"In going through the towns of France some time since, I could not help observing how much plainer their parrots spoke than ours, and how very distinctly I understood their parrots speak French when I could not understand our own, though they spoke my native language. I at first ascribed it to the different qualities of the two languages, and was for entering into an elaborate discussion on the vowels and consonants; but a friend that was with me solved the difficulty at once, by assuring me that the French women scarce did anything else the whole day than sit and instruct their feathered pupils; and that the birds were thus distinct in their lessons in consequence of continual schooling."

His tour does not seem to have left in his memory the most fragrant recollections; for being asked, after his return, whether travelling on the continent repaid "an Englishman for the privations and annoyances attendant on it," he replied, "I recommend it by all means to the sick, if they are without the sense of *smelling*, and to the poor, if they are without the sense of *feeling*; and to both if they can discharge from their

minds all idea of what in England we term comfort."

It is needless to say, that the universal improvement in the art of living on the continent has at the present day taken away the force of Goldsmith's reply, though even at the time it was more humorous than correct.

### CHAP. XXX

Death of Goldsmith's mother—Biography of Parnell—Agreement with Davies for the "History of Rome"—"Life of Bolingbroke"—The "Haunch of Venison."

On his return to England, Goldsmith received the melancholy tidings of the death of his mother. Notwithstanding the fame as an author to which he had attained, she seems to have been disappointed in her early expectations from him. Like others of his family, she had been more vexed by his early follies than pleased by his proofs of genius; and in subsequent years, when he had risen to fame and to intercourse with the great, had been annoyed at the ignorance of the world and want of management which prevented him from pushing his fortune. He had always, however, been an affectionate son, and in the latter years of her life, when she had become blind, contributed from his precarious resources to prevent her from feeling want.

He now resumed the labours of the pen, which his recent excursion to Paris rendered doubly necessary. We should have mentioned a "Life of Parnell," published by him shortly after the "Deserted Village." It was, as usual, a piece of job-work, hastily got up for pocket-money. Johnson spoke slightly of it, and the author himself thought proper to apologise for its meagreness; yet, in so doing, used a simile, which, for beauty of imagery and felicity of language, is enough of itself to stamp a value upon the essay:—

"Such," says he, "is the very unpoetical detail of the life of a poet. Some dates and some few facts, scarcely more interesting than those that make the ornaments of a country tombstone, are all that remain of one whose labours now begin to excite universal curiosity. A poet, while living, is seldom an object sufficiently great to attract much attention; his real merits are known but to a few; and these are generally sparing in their praises. When his fame is increased by time, it is then too late to investigate the peculiarities of his disposition; *the deus of morning are past, and we vainly try to continue the chase by the meridian splendour.*"

He now entered into an agreement with Davies to prepare an abridgment, in one volume duodecimo, of his "History of Rome;" but first to write a work for which there was more immediate demand. Davies was about to republish Lord Bolingbroke's "Dissertation on Parties," which he conceived would be exceedingly applicable to the affairs of the day, and make a probable hit during the existing state of violent political excitement; to give it still greater effect and currency, he engaged Goldsmith to introduce it with a prefatory life of Lord Bolingbroke.

About this time Goldsmith's friend and countryman, Lord Clare, was in great affliction, caused by the death of his only son, Colonel Nugent, and stood in need of the sympathies of a kind-hearted friend. At his request, therefore, Goldsmith paid him a visit at his noble seat of Gosford, taking his tasks with him. Davies was in a worry lest Gosford Park should prove a Caqua to the poet, and the time be lost. "Dr. Goldsmith," writes he to a friend, "has gone with Lord Clare into the country, and I am plagued to get the proofs from him of the 'Life of Lord Bolingbroke.'" The proofs, however, were furnished in time for the publication of the work in December. The biography, though written during a time of political turmoil, and introducing a work intended to be thrown into the arena

of politics, maintained that freedom from party prejudice observable in all the writings of Goldsmith. It was a selection of facts, drawn from many unreadable sources, and arranged into a clear, flowing narrative, illustrative of the career and character of one, who, as he intimates, "seemed formed by nature to take delight in struggling with opposition; whose most agreeable hours were passed in storms of his own creating; whose life was spent in a continual conflict of politics, and as if that was too short for the combat, has left his memory as a subject of lasting contention." The sum received by the author for this memoir is supposed, from circumstances, to have been forty pounds.

Goldsmith did not find the residence among the great unattended with mortifications. He had now become accustomed to be regarded in London as a literary lion, and he was annoyed at what he considered a slight on the part of Lord Camden. He complained of it on his returned to town at a party of his friends. "I met him," said he, "at Lord Clare's house in the country; and he took no more notice of me than if I had been an ordinary man." "The company," says Boswell, "laughed heartily at this piece of diverting simplicity." And foremost among the laughers was doubtless the rattled Boswell. Johnson, however, stepped forward, as usual, to defend the poet, whom he would allow no one to assail but himself; perhaps in the present instance he thought the dignity of literature itself involved in this question. "Nay, gentlemen," roared he, "Dr. Goldsmith is in the right. A nobleman ought to have made up to such a man as Goldsmith, and I think it is much against Lord Camden that he neglected him."

After Goldsmith's return to town he received from Lord Clare a present of game, which he has celebrated and perpetuated in his amusing verses, entitled the "Haunch of Venison." Some of the lines pleasantly set forth the embarrassment caused by the appearance of such an aristocratic delicacy in the humble kitchen of a poet, accustomed to look up to mutton as a treat:—

Thanks, my lord, for your venison; for finer or fatter  
Never ranged in a forest or smoked in a platter:  
The haunch was a picture for painters to study,  
The fat was so white, and the lean was so ruddy;  
Though my stomach was sharp, I could scarce help regretting  
To spoil such a delicate picture by eating:  
I had thought in my chambers to place it in view,  
To be shown to my friends as a piece of "vertu";  
As in some Irish houses where things are so-so,  
One gammon of bacon hangs up for a show;  
But, for eating a rasher of what they take pride in,  
They'd as soon think of eating the pan it was fried in.

But hang it—to poets, who seldom can eat,  
Your very good mutton's a very good treat;  
Such dainties to them, their health it might hurt;  
It's like sending them ruffles when wanting a shirt.

We have an amusing anecdote of one of Goldsmith's blunders, which took place on a subsequent visit to Lord Clare's when that nobleman was residing in Bath.

Lord Clare and the Duke of Northumberland had houses next to each other, of similar architecture. Returning home one morning from an early walk, Goldsmith, in one of his frequent fits of absence, mistook the house, and walked up into the duke's dining-room, where he and the duchess were about to sit down to breakfast. Goldsmith, still supposing himself in the house of Lord Clare, and that they were visitors, made them an easy salutation, being acquainted with them, and threw himself on a sofa in the lounging manner of a man perfectly at home. The duke and duchess soon perceived his mistake, and while they smiled internally, endeavoured, with the considerateness of well-bred people, to prevent any awkward embarrassment. They chatted sociably with him about matters in Bath, until, breakfast being served, they invited him to partake. The truth at once flashed upon poor heedless Goldsmith; he started up from his free-and-easy position, made a con-

fused apology for his blunder, and would have retired perfectly disconcerted, had not the duke and duchess treated the whole as a lucky occurrence to throw him in their way, and exacted a promise from him to dine with them.

This may be hung up as a companion-piece to his blunder on his first visit to Northumberland House.

#### CHAP. XXXI.

Dinner at the Royal Academy—The Rowley controversy—Horace Walpole's conduct to Chatterton—Johnson at Redcliffe church—Goldsmith's "History of England"—Davies's criticism—Letter to Bennet Langton.

On St. George's-day of this year (1771), the first annual banquet of the Royal Academy was held in the exhibition-room, the walls of which were covered with works of art, about to be submitted to public inspection. Sir Joshua Reynolds, who first suggested this elegant festival, presided in his official character; Drs. Johnson and Goldsmith, of course, were present, as professors of the academy; and beside the academicians, there was a large number of the most distinguished men of the day as guests. Goldsmith on this occasion drew on himself the attention of the company, by launching out with enthusiasm on the poems recently given to the world by Chatterton, as the works of an ancient author by the name of Rowley, discovered in the tower of Redcliffe Church, at Bristol. Goldsmith spoke of them with rapture, as a treasure of old English poetry. This immediately raised the question of their authenticity, they having been pronounced a forgery of Chatterton's. Goldsmith was warm for their being genuine. When he considered, he said, the merit of the poetry, the acquaintance with life and the human heart displayed in them, the antique quaintness of the language, and the familiar knowledge of historical events of their supposed day, he could not believe it possible they could be the work of a boy of sixteen, of narrow education, and confined to the duties of an attorney's office. They must be the productions of Rowley.

Johnson, who was a stout unbeliever in Rowley, as he had been in Ossian, rolled in his chair and laughed at the enthusiasm of Goldsmith. Horace Walpole, who sat near by, joined in the laugh and jeer as soon as he found that the "*trouvaille*," as he called it, "of his friend Chatterton" was in question. This matter, which had excited the simple admiration of Goldsmith, was no novelty to him he said. "He might, had he pleased, have had the honour of ushering the great discovery to the learned world." And so he might had he followed his own impulse in the matter, for he himself had been an original believer; had pronounced some specimen verses sent to him by Chatterton wonderful for their harmony and spirit; and had been ready to print them and publish them to the world with his sanction. When he found, however, that his unknown correspondent was a mere boy, humble in sphere and indigent in circumstances, and when Gray and Mason pronounced the poems forgeries, he had changed his whole conduct towards the unfortunate author, and by his neglect and coldness had dashed all his sanguine hopes to the ground.

Exulting in his superior discernment, this cold-hearted man of society now went on to divert himself as he says with the credulity of Goldsmith, whom he was accustomed to pronounce "an inspired idiot;" but his mirth was soon dashed, for on asking the poet what had become of this Chatterton, he was answered, doubtless in the feeling tone of one who had experienced the pangs of desponding genius, that "he had been to London, and had destroyed himself."

The reply struck a pang of self-reproach even to the cold heart of Walpole; a faint blush may have visited

his cheek at his recent levity. "The persons of honour and veracity who were present," said he, in after years, when he found it necessary to exculpate himself from the charge of heartless neglect of genius, "will attest with what surprise and concern I thus first heard of his death." Well might he feel concern. His cold neglect had doubtless contributed to madden the spirit of that youthful genius, and hurry him towards his untimely end; nor have all the excuses and palliations of Walpole's friends and admirers been ever able entirely to clear this stigma from his fame.

But what was there in this enthusiasm and credulity of honest Goldsmith in this matter, to subject him to the laugh of Johnson or the railery of Walpole? Granting the poems were not ancient, were they not good? Granting they were not the productions of Rowley, were they the less admirable for being the productions of Chatterton? Johnson himself testified to their merits and the genius of their composer, when some years afterwards, he visited the tower of Redcliffe church, and was shown the coffer in which poor Chatterton had pretended to find them. "This," said he, "is the most extraordinary young man that has encountered my knowledge. *It is wonderful how the whelp has written such things.*"

As to Goldsmith, he persisted in his credulity, and had subsequently a dispute with Dr. Percy on the subject, which interrupted and almost destroyed their friendship. After all, his enthusiasm was of a generous, poetic kind; the poems remain beautiful monuments of genius, and it is even now difficult to persuade oneself that they could be entirely the productions of a youth of sixteen.

In the month of August was published anonymously the History of England, on which Goldsmith had been for some time employed. It was in four volumes, compiled chiefly, as he acknowledged in the preface, from Rapin, Carle, Smollett, and Hume, "each of whom," says he, "have their admirers, in proportion as the reader is studious of political antiquities, fond of minute anecdote, a warm partisan, or a deliberate reasoner." It possessed the same kind of merit as his other historical compilations—a clear, succinct narrative, a simple, easy, and graceful style, and an agreeable arrangement of facts; but was not remarkable for either depth of observation or minute accuracy of research. Many passages were transferred, with little if any alteration, from his "Letters from a Nobleman to his Son" on the same subject. The work, though written without party feeling, met with sharp animadversions from political scribblers. The writer was charged with being unfriendly to liberty, disposed to elevate monarchy above its proper sphere; a tool of ministers—one who would betray his country for a pension. Tom Davies, the publisher, the pompous little bibliopole of Russell-street, alarmed lest the book should prove unsaleable, undertook to protect it by his pen, and wrote a long article in its defence in "The Public Advertiser." He was vain of his critical effusion, and sought by nods and winks and innuendoes to intimate his authorship. "Have you seen," said he in a letter to a friend, "An Impartial Account of Goldsmith's History of England? If you want to know who was the writer of it, you will find him in Russell-street;—but, *num!*"

The history, on the whole, however, was well received; some of the critics declared that English History had never before been so usefully, so elegantly, and agreeably epitomised; and, like his other historical writings, it has kept its ground in English literature.

Goldsmith had intended this summer, in company with Sir Joshua Reynolds, to pay a visit to Bennet Langton, at his seat in Lincolnshire, where he was settled in domestic life, having the year previously married the Countess Dowager of Rothes. The following letter, however, dated from his chambers in the Temple, on the 7th of September, apologises for putting off the

visit, while it gives an amusing account of his summer occupations and of the attacks of the critics on his "History of England."

"MY DEAR SIR,—Since I had the pleasure of seeing you last, I have been almost wholly in the country at a farmer's house, quite alone, trying to write a comedy. It is now finished; but when or how it will be acted, or whether it will be acted at all, are questions I cannot resolve. I am therefore so much employed upon that, that I am under the necessity of putting off my intended visit to Lincolnshire for this season. Reynolds is just returned from Paris, and finds himself now in the case of a truant that must make up for his idle time by diligence. We have therefore agreed to postpone our journey till next summer, when we hope to have the honour of waiting upon Lady Rother and you, and staying double the time of our late intended visit. We often meet, and never without remembering you. I see Mr. Beauclerc very often both in town and country. He is now going directly forward to become a second Boyle—deep in chemistry and physics. Johnson has been down on a visit to a country parson, Dr. Taylor; and is returned to his old haunts at Mrs. Thrall's. Burke is a farmer, *an attendant* a better place; but visiting about too. Every soul is visiting about and merry but myself. And that is hard, too, as I have been trying these three months to do something to make people laugh. There have I been strolling about the hedges, studying jests with a most tragical countenance. The 'Natural History' is about half finished, and I will shortly finish the rest. God knows I am tired of this kind of finishing, which is but bungling work; and that not so much my fault as the fault of my scurvy circumstances. They begin to talk in town of the Opposition's gaining ground; the cry of liberty is still as loud as ever. I have published, or Davies has published for me, an 'Abridgment of the History of England,' for which I have been a good deal abused in the newspapers for betraying the liberties of the people. God knows I had no thought for or against liberty in my head—my whole aim being to make up a book of a decent size, that, as Squire Richard says, '*would do no harm to nobody*.' However, they set me down as an arrant Tory, and consequently an honest man. When you come to look at any part of it, you'll say that I am a sore Whig. God bless you, and with my most respectful compliments to her ladyship, I remain, dear Sir, your most affectionate humble servant,  
"OLIVER GOLDSMITH."

#### CHAP. XXXII.

Marriage of *Little Comedy*—Goldsmith at Barton—Practical jokes at the expenses of his toilet—Amusements at Barton—Aquatic misadventure.

Though goldsmith found it impossible to break from his literary occupations to visit Bennet Langton in Lincolnshire, he soon yielded to attractions from another quarter, in which somewhat of sentiment may have mingled. Miss Catherine Horneck, one of his beautiful fellow-travellers, otherwise called *Little Comedy*, had been married in August to Henry William Bunbury, Esq., a gentleman of fortune, who has become celebrated for the humorous productions of his pencil. Goldsmith was shortly afterwards invited to pay the newly-married couple a visit at their seat, at Barton, in Suffolk. How could he resist such an invitation—especially as the *Jessamy Bride* would of course be among the guests? It is true, he was hampered with work; he was still more hampered with debt; his accounts with Newbery were perplexed, but all must give way. New advances are procured from Newbery on the promise of a new tale in the style of the *Vicar of Wakefield*, of which he showed him a few roughly-

sketched chapters; so, his purse replenished in the old way, "by hook or by crook," he posted off to visit the bride at Barton. He found there a joyous household, and one where he was welcomed with affection. Garrick was there, and played the part of master of the revels, for he was an intimate friend of the master of the house. Notwithstanding early misunderstandings, a social intercourse between the actor and the poet had grown up of late, from their meeting together continually in the same circle. A few particulars have reached us concerning Goldsmith while on this happy visit. We believe the legend has come down from Miss Mary Horneck herself. "While at Barton," she says, "his manners were always playful and amusing, taking the lead in promoting any scheme of innocent mirth, and usually prefacing the invitation with 'Come, now, let us play the fool a little.' At cards, which was commonly a round game, and the stake small, he was always the most noisy, affected great eagerness to win, and teased his opponents of the gentler sex with continual jest and banter on their want of spirit in not risking the hazards of the game. But one of his most favourite enjoyments was to romp with the children, when he threw off all reserve, and seemed one of the most joyous of the group.

"One of the means by which he amused us was his songs, chiefly of the comic kind, which were sung with some taste and humour: several, I believe, were of his own composition, and I regret that I neither have copies, which might have been readily procured from him at the time, nor do I remember their names."

His perfect good humour made him the object of tricks of all kinds—often in retaliation of some prank which he himself had played off. Unluckily, these tricks were sometimes made at the expense of his toilet, which, with a view peradventure to please the eye of a certain fair lady, he had again enriched to the impoverishment of his purse. "Being at all times gay in his dress," says this lady-like legend, "he made his appearance at the breakfast-table in a smart black silk coat with an expensive pair of ruffles; the coat some one contrived to soil, and it was sent to be cleansed; but, either by accident, or probably by design, the day after it came home the sleeves became daubed with paint, which was not discovered until the ruffles also, to his great mortification, were irretrievably disfigured.

"He always wore a wig—a peculiarity which those who judge of his appearance only from the fine poetical head of Reynolds would not suspect; and on one occasion some person contrived seriously to injure this important adjunct to dress. It was the only one he had in the country, and the misfortune seemed irreparable until the services of Mr. Bunbury's valet were called in, who, however, performed his functions so indifferently, that poor Goldsmith's appearance became the signal for a general smile."

This was wicked waggery, especially when it was directed to mar all the attempts of the unfortunate poet to improve his personal appearance, about which he was at all times dubiously sensitive, and particularly when among the ladies.

We have in a former chapter recorded his unlucky tumble into a fountain at Versailles, when attempting a feat of agility in presence of the fair Hornecks. Water was destined to be equally baneful to him on the present occasion. "Some difference of opinion," says the fair narrator, "having arisen with Lord Harrington respecting the depth of a pond, the poet remarked that it was not so deep but that, if anything valuable was to be found at the bottom, he would not hesitate to pick it up. His lordship, after some banter, threw in a guinea; Goldsmith, not to be out-done in this kind of bravado, in attempting to fulfil his promise without getting wet, accidentally fell in, to the amusement of all present, but persevered, brought out the money, and kept it, remarking that he had abundant objects on whom to bestow

any further proofs of his lordship's whim or bounty."

All this is recorded by the beautiful Mary Horneck, the Jessamy Bride herself; but while she gives these amusing pictures of poor Goldsmith's eccentricities, and of the mischievous pranks played off upon him, she bears unqualified testimony, which we have quoted elsewhere, to the qualities of his head and heart, which shone forth in his countenance, and gained him the love of all who knew him.

Among the circumstances of this visit vaguely called to mind by this fair lady in after years, was that Goldsmith read to her and her sister the first part of a novel which he had in hand. It was doubtless the manuscript mentioned at the beginning of this chapter, on which he had obtained an advance of money from Newbery to stave off some pressing debts, and to provide funds for this very visit. It never was finished. The bookseller, when he came afterwards to examine the manuscript, objected to it as a mere narrative version of the "Good-natured Man." Goldsmith, too easily put out of conceit of his writings, threw it aside, forgetting that this was the very Newbery who kept his Vicar of Wakefield by him nearly two years through doubts of its success. The loss of the manuscript is deeply to be regretted; it doubtless would have been properly wrought up before given to the press, and might have given us new scenes in life and traits of character, while it could not fail to bear traces of his delightful style. What a pity he had not been guided by the opinions of his fair listeners at Barton, instead of that of the astute Mr. Newbery!

#### CHAP. XXXIII.

Dinner at General Oglethorpe's—Anecdotes of the General—  
Dispute about duelling—Ghost stories

We have mentioned old General Oglethorpe as one of Goldsmith's aristocratical acquaintances. This veteran, born in 1698, had commenced early life by serving, when a mere stripling, under Prince Eugene against the Turks. He had continued in military life, and been promoted to the rank of major-general in 1745, and received a command during the Scottish rebellion. Being of strong Jacobite tendencies, he was suspected and accused of favouring the rebels; and, though acquitted by a court of inquiry, was never afterwards employed—or, in technical language, was shelved. He had since been repeatedly a member of parliament, and had always distinguished himself by learning, taste, active-benevolence, and high Tory principles. His name, however, has become historical, chiefly from his transactions in America, and the share he took in the settlement of the colony of Georgia. It lies embalmed in honourable immortality in a single line of Pope's:—

One, driven by strong benevolence of soul,  
Shall fly, like Oglethorpe, from pole to pole.

The veteran was now seventy-four years of age, but healthy and vigorous, and as much the preux chevalier as in his younger days, when he served with Prince Eugene. His table was often the gathering-place of men of talent. Johnson was frequently there, and delighted in drawing from the General details of his various "experiences." He was anxious that he should give the world his life. "I know no man," said he, "whose life would be more interesting." Still the vivacity of the general's mind and the variety of his knowledge made him skip from subject to subject too fast for the lexicographer. "Oglethorpe," growled he, "never completes what he has to say."

Boswell gives us an interesting and characteristic account of a dinner party at the general's (April 10th, 1772), at which Goldsmith and Johnson were present. After dinner, when the cloth was removed, Oglethorpe,

at Johnson's request, gave an account of the siege of Belgrade, in the true veteran style. Pouring a little wine upon the table, he drew his lines and parallels with a wet finger, describing the positions of the opposing forces. "Here were we—here were the Turks," to all which Johnson listened with the most earnest attention, poring over the plans and diagrams with his usual purblind closeness.

In the course of conversation the general gave an anecdote of himself in early life, when serving under Prince Eugene. Sitting at table once in company with a prince of Wurtemberg, the latter gave a fillip to a glass of wine, so as to make some of it fly in Oglethorpe's face. The manner in which it was done was somewhat equivocal. How was it to be taken by the stripling officer? If seriously, he must challenge the prince; but in so doing he might fix on himself the character of a draw-can-sir. If passed over without notice, he might be charged with cowardice. His mind was made up in an instant. "Prince," said he, smiling, "that is an excellent joke; but we do it much better in England." So saying, he threw a whole glass of wine in the prince's face. "Il a bien fait, mon prince," cried an old general present, "vous l'avez commencé." (He has done right, my prince; you commenced it.) The prince had the good sense to acquiesce in the decision of the veteran, and Oglethorpe's retort in kind was taken in good part.

It was probably at the close of this story that the officious Boswell, ever anxious to promote conversation for the benefit of his note-book, started the question whether duelling were consistent with moral duty. The old general fired up in an instant. "Undoubtedly," said he, with a lofty air; "undoubtedly a man has a right to defend his honour." Goldsmith immediately carried the war into Boswell's own quarters, and pinned him with the question, "what he would do if affronted?" The pliant Boswell, who for the moment had the fear of the general rather than of Johnson before his eyes, replied, "he should think it necessary to fight." "Why, then, that solves the question," replied Goldsmith. "No, sir!" thundered out Johnson; "it does not follow that what a man would do is therefore right." He, however, subsequently went into a discussion to show that there were necessities in the case, arising out of the artificial refinement of society, and its proscription of any one who should put up with an affront without fighting a duel. "He, then," concluded he, "who fights a duel does not fight from passion against his antagonist, but out of self-defence, to avert the stigma of the world, and to prevent himself from being driven out of society. I could wish there were not that superfluity of refinement; but while such notions prevail, no doubt a man may lawfully fight a duel."

Another question started was, whether people who disagreed on a capital point could live together in friendship. Johnson said they might. Goldsmith said they could not, as they had not the *idem velle atque idem velle*—the same likings and aversions. Johnson rejoined, that they must shun the subject on which they disagreed. "But, sir," said Goldsmith "when people live together who have something as to which they disagree, and which they want to shun, they will be in the situation mentioned in the story of Blue Beard—'you may look into all the chambers but one;' but we should have the greatest inclination to look into that chamber, to talk of that subject." "Sir," thundered Johnson, in a loud voice, "I am not saying that you could live in friendship with a man from whom you differ as to some point; I am only saying that I could do it."

Who will not say that Goldsmith had not the best of this petty contest? How just was his remark! how felicitous the illustration of the blue chamber! how rude and overbearing was the *argumentum ad hominem* of Johnson, when he felt that he had the worst of the argument!

The conversation turned upon ghosts. General Oglethorpe told the story of a Colonel Pendergast, an officer in the Duke of Marlborough's army, who predicted among his comrades that he should die on a certain day. The battle of Malplaquet took place on that day. The colonel was in the midst of it, but came out unhurt. The firing had ceased, and his brother officers jested with him about the fallacy of his prediction. "The day is not over," replied he, gravely; "I shall die, notwithstanding what you see." His words proved true. The order for a cessation of firing had not reached one of the French batteries, and a random shot from it killed the colonel on the spot. Among his effects was found a pocket-book in which he had made a solemn entry, that, Sir John Friend, who had been executed for high treason, had appeared to him, either in a dream or vision, and predicted that he would meet him on a certain day (the very day of the battle). Colonel Cecil, who took possession of the effects of Colonel Pendergast, and read the entry in the pocket-book, told this story to Pope, the poet, in the presence of General Oglethorpe.

This story, as related by the general, appears to have been well received, if not credited, by both Johnson and Goldsmith, each of whom had something to relate in kind. Goldsmith's brother, the clergyman in whom he had such implicit confidence, had assured him of his having seen an apparition. Johnson, also, had a friend, old Mr. Cave, the printer, at St. John's Gate, "an honest man and a sensible man," who told him he had seen a ghost: he did not, however, like to talk of it, and seemed to be in great horror whenever it was mentioned. "And pray, sir," asked Boswell, "what did he say was the appearance?" "Why, sir, something of a shadowy being."

The reader will not be surprised at this superstitious turn in the conversation of such intelligent men, when he recollects that, but a few years before this time, all London had been agitated by the absurd story of the Cock-lane ghost; a matter which Dr. Johnson had deemed worthy of his serious investigation, and about which Goldsmith had written a pamphlet.

#### CHAP. XXXIV.

Mr. Joseph Cradock—An author's confidings—An amanuensis—Life at Edgeware—Goldsmith conjuring—George Colman—The Fantoccini.

Among the agreeable acquaintances made by Goldsmith about this time was a Mr. Joseph Cradock, a young gentleman of Leicestershire, living at his ease, but disposed to "make himself uneasy" by meddling with literature and the theatre; in fact, he had a passion for plays and players, and had come up to town with a modified translation of Voltaire's tragedy of Zobeide, with a view to get it acted. There was no great difficulty in the case, as he was a man of fortune, had letters of introduction to persons of note, and was altogether in a different position from the indigent man of genius who managers might harass with impunity. Goldsmith met him at the house of Yates, the actor, and finding that he was a friend of Lord Clare, soon became sociable with him. Mutual tastes quickened the intimacy, especially as they found means of serving each other. Goldsmith wrote an epilogue for the tragedy of Zobeide; and Cradock, who was an amateur musician, arranged the music for the Threnodia Augustalis, a lament on the death of the princess Dowager of Wales, the political mistress and patron of Lord Clare, which Goldsmith had thrown off hastily to please that nobleman. The tragedy was played with some success at Covent Garden; the lament was recited and sung at Mrs. Corne's rooms—a very fashionable resort in Soho square, got up by a woman of enterprise of that name. It was in whimsical parody of those gay and somewhat

promiscuous assemblages that Goldsmith used to call the motley evening parties at his lodgings "little Cornelys."

The Threnodia Augustales was not publicly known to be by Goldsmith until several years after his death.

Cradock was one of the few polite intimates who left more disposed to sympathise with the generous qualities of the poet than to sport with his eccentricities. He sought his society whenever he came to town, and occasionally had him to his seat in the country. Goldsmith appreciated his sympathy, and unburdened himself to him without reserve. Seeing the lettered ease in which this amateur author was enabled to live, and the time he could bestow on the elaboration of a manuscript, "Ah! Mr. Cradock," cried he, "think of me, that must write a volume every month!" He complained to him of the attempts made by inferior writers, and by others who could scarcely come under that denomination, not only to abuse and depreciate his writings, but to render him ridiculous as a man; perverting every harmless sentiment and action into charges of absurdity, malice, or folly. "Sir," said he, in the fulness of his heart, "I am as a lion baited by curs!"

Another acquaintance which he made about this time was a young countryman of the name of M'Donnell, whom he met in a state of destitution, and, of course, befriended. The following grateful recollections of his kindness and his merits were furnished by that person in after years:—

"It was in the year 1772," writes he, "that the death of my elder brother—when in London, on my way to Ireland—left me in a most forlorn situation. I was then about eighteen; I possessed neither friends nor money, nor the means of getting to Ireland, of which or of England I knew scarcely anything, from having so long resided in France. In this situation I had strolled about for two or three days, considering what to do, but unable to come to any determination, when Providence directed me to the Temple Gardens. I threw myself on a seat, and, willing to forget my miseries for a moment, drew out a book; that book was a volume of Boileau. I had not been there long when a gentleman, strolling about, passed near me, and observing, perhaps, something Irish or foreign in my garb or countenance, addressed me. 'Sir, you seem studious; I hope you find this a favourable place to pursue it.' 'Not very studious, sir; I fear it is the want of society that brings me hither; I am solitary and unknown in this metropolis;' and a passage from Cicero—*Oratio pro Archia*—occurring to me, I quoted it; *Hæc studia promoucant nobiscum, pergrinuntur, rusticantur*. 'You are a scholar, too, sir, I perceive.' 'A piece of one, sir; but I ought still to have been in the college where I had the good fortune to pick up the little I know.' A good deal of conversation ensued; I told him part of my history, and he, in return, gave his address in the Temple, desiring me to call soon, from which, to my infinite surprise and gratification, I found that the person who thus seemed to take an interest in my fate was my countryman, and a distinguished ornament of letters.

"I did not fail to keep the appointment, and was received in the kindest manner. He told me smilingly that he was not rich; that he could do little for me in direct pecuniary aid, but would endeavour to put me in the way of doing something for myself; observing, that he could at least furnish me with advice not wholly useless to a young man placed in the heart of the great metropolis. 'In London,' he continued, 'nothing is to be got for nothing: you must work; and no man who chooses to be industrious need be under obligations to another, for here labour of every kind commands its reward. If you think proper to assist me occasionally as amanuensis, I shall be obliged, and you will be placed under no obligation, until something more permanent can be secured for you.' This employment, which I pursued for some time, was to translate passages from

Buffon, which was abridged or altered, according to circumstances, for his "Natural History."

Goldsmith's literary tasks were fast getting a-head of him, and he began now to "toil after them in vain."

Five volumes of the "Natural History" here spoken of had long since been paid for by Mr. Griffin, yet most of them were still to be written. His young amanuensis bears testimony to his embarrassments and perplexities, but to the degree of equanimity with which he bore them:—

"It has been said," observes he, "that he was irritable. Such may have been the case at times; nay, I believe it was so; for what with the continual pursuit of authors, printers, and booksellers, and occasional pecuniary embarrassments, few could have avoided exhibiting similar marks of impatience. But it was never so towards me. I saw him only in his bland and kind moods, with a flow, perhaps an overflow, of the milk of human kindness for all who were in any manner dependent upon him. I looked upon him with awe and veneration, and he upon me as a kind parent upon a child.

"His manner and address exhibited much frankness and cordiality, particularly to those with whom he possessed any degree of intimacy. His good-nature was equally apparent. You could not dislike the man, although several of his follies and foibles you might be tempted to condemn. He was generous and inconsiderate: money with him had little value."

To escape from many of the tormentors just alluded to, and to devote himself without interruption to his task, Goldsmith took lodgings for the summer in a farmhouse, near the six-mile stone on the Edgware-road, and carried down his books in two return post-chaises. He used to say he believed the farmer's family thought him an odd character, similar to that in which the *Spectator* appeared to his landlady and her children—he was *The Gentleman*. Boswell tells us that he went to visit him at the place in company with Mickle, translator of the *Lusiad*. Goldsmith was not at home. Having a curiosity to see his apartment, however, they went in, and found curious scraps of descriptions of animals scrawled upon the wall with a black lead pencil.

The farm-house in question is still in existence, though much altered. It stands upon a gentle eminence, in Hyde-lane, commanding a pleasant prospect towards Hendon. The room is still pointed out in which "*She Stoops to Conquer*" was written; a convenient and airy apartment, up one flight of stairs.

Some matter-of-fact traditions concerning the author were furnished, a few years since, by a son of the farmer, who was sixteen years of age at the time Goldsmith resided with his father. Though he had engaged to board with the family, his meals were generally sent to him in his room, in which he passed the most of his time, negligently dressed, with his shirt collar open, busily engaged in writing. Sometimes, probably when in moods of composition, he would wander into the kitchen, without noticing any one, stand musing with his back to the fire, and then hurry off again to his room—no doubt to commit to paper some thought which had struck him.

Sometimes he strolled about the fields, or was to be seen loitering and reading and musing under the hedges. He was subject to fits of wakefulness, and read much in bed; if not disposed to read he still kept the candle burning; if he wished to extinguish it, and it was out of his reach, he flung his slipper at it, which would be found in the morning near the overturned candlestick and daubed with grease. He was noted here, as everywhere else, for his charitable feelings. No beggar applied to him in vain, and he evinced on all occasions great commiseration for the poor.

He had the use of the parlour to receive and entertain

company, and was visited by Sir Joshua Reynolds, Hugh Boyd, the reputed author of *Junius*, Sir William Chambers, and other distinguished characters. He gave occasionally, though rarely, a dinner-party; and on one occasion, when his guests were detained by a thunder-shower, he got up a dance, and carried the merriment late into the night.

As usual, he was the promoter of hilarity among the young, and at one time took the children of the house to see a company of strolling players at Hendon. The greatest amusement to the party, however, was derived from his own jokes on the road and his comments on the performance, which produced infinite laughter among his youthful companions.

Near to his rural retreat at Edgware, a Mr. Seguin, an Irish merchant of literary tastes, had country quarters for his family, where Goldsmith was always welcome.

In this family he would indulge in playful and even grotesque humour, and was ready for anything—conversation, music, or a game of romps. He prided himself upon his dancing, and would walk a minuet with Mrs. Seguin, to the infinite amusement of herself and the children, whose shouts of laughter he bore with perfect good-humour. He would sing Irish songs, and the Scotch ballad of Johnny Armstrong. He took the lead in the children's sports of blind man's buff, hunt the slipper, &c., or in their games at cards, and was the most noisy of the party, affecting to cheat, and to be excessively eager to win; while with children of smaller size he would turn the hind part of his wig before, and play all kinds of tricks to amuse them.

One word as to his musical skill and his performance on the flute, which comes up so invariably in all his fireside revels. He really knew nothing of music scientifically; he had a good ear, and may have played sweetly; but we are told he could not read a note of music. Roubillac, the statuary, once played a trick upon him in this respect. He pretended to score down an air as the poet played it, but put down crotchets and semibreves at random. When he had finished, Goldsmith cast his eyes over it and pronounced it correct! It is possible that his execution in music was like his style in writing—in sweetness and melody he may have snatched a grace beyond the reach of art!

He was at all times a capital companion for children, and knew how to fall in with their humours. "I little thought," said Miss Hawkins, the woman grown, "what I should have to boast when Goldsmith taught me to play Jack and Jill by two bits of paper on his fingers." He entertained Mrs. Garrick, we are told, with a whole budget of stories and songs; delivered the "*Chimney Sweep*" with exquisite taste as a solo; and performed a duet with Garrick of "*Old Rose and Burn the Bellows*."

"I was only five years old," says the late George Colman, "when Goldsmith, one evening when drinking coffee with my father, took me on his knee and began to play with me, which amiable act I returned with a very smart slap of the face; it must have been a tingler, for I left the marks of my little spiteful paw upon his cheek. This infantile outrage was followed by summary justice, and I was locked up by my father in an adjoining room, to undergo solitary imprisonment in the dark. Here I began to howl and scream most abominably. At length, a friend appeared to extricate me from jeopardy: it was the good-natured doctor himself, with a lighted candle in his hand, and a smile upon his countenance, which was still partially red from the effects of my petulance. I sulked and sobbed, and he fondled and soothed until I began to brighten. He seized the propitious moment, placed three hats upon the carpet, and a shilling under each; the shillings, he told me, were England, France, and Spain. 'Hey, presto, cockorum!' cried the doctor, and, lo! on uncovering the shillings they were all found congregated under one. I was no politician at the time, and therefore might not

have wondered at the sudden revolution which brought England, France, and Spain all under one crown; but, as I was also no conjuror, it amazed me beyond measure. From that time, whenever the doctor came to visit my father,

I pluck'd his gown to share the good man's smile;  
a game of romps constantly ensued, and we were always cordial friends and merry playfellows."

Although Goldsmith made the Edgeware farm-house his head-quarters for the summer, he would absent himself for weeks at a time on visits to Mr. Cradock, Lord Clare, and Mr. Langton, at their country-seats. He would often visit town, also, to dine and partake of the public amusements. On one occasion he accompanied Edmund Burke to witness a performance of the Italian Fantoccini, or puppets, in Pantion-street—an exhibition which had hit the caprice of the town, and was in great vogue. The puppets were set in motion by wires, so well concealed as to be with difficulty detected. Boswell, with his usual obtuseness with respect to Goldsmith, accuses him of being jealous of the puppets! "When Burke," said he, "praised the dexterity with which one of them tossed a pike, 'Pshaw,' said Goldsmith *with some warmth*, 'I can do it better myself.'" "The same evening," adds Boswell, "when supping at Burke's lodgings, he broke his shin by attempting to exhibit to the company how much better he could jump over a stick than the puppets."

Goldsmith jealous of puppets! This even passes in absurdity Boswell's charge upon him of being jealous of the beauty of the two Miss Hornecks.

The Pantion-street puppets were destined to be a source of further amusement to the town, and of annoyance to the little autocrat of the stage. Foote, the Aristophanes of the English drama, who was always on the alert to turn every subject of popular excitement to account, seeing the success of the Fantoccini, gave out that he should produce a Primitive Puppet-show at the Haymarket, to be entitled "The Handsome Chambermaid, or Piety in Pattens," intended to burlesque the *sentimental Comedy* which Garrick still maintained at Drury Lane. The idea of a play to be performed in a regular theatre by puppets excited the curiosity and talk of the town. "Will your puppets be as large as life, Mr. Foote?" demanded a lady of rank. "Oh, no, my lady," replied Foote, "*not much larger than Garrick.*"

#### CHAP. XXXV.

Broken health—Dissipation and debts—The Irish widow—Practical jokes—A misquoted pun—Malagrida—Goldsmith proved to be a fool—Distressed ballad-singers—The poet at Ranelagh.

Goldsmith returned to town in the autumn (1772), with his health much disordered. His close fits of sedentary application, during which he in a manner tied himself to the mast, had laid the seeds of a lurking malady in his system, and produced a severe illness in the course of the summer. Town life was not favourable to the health either of body or mind. He could not resist the siren voice of temptation, which, now that he had become a notoriety, assailed him on every side. Accordingly we find him launching away in a career of social dissipation; dining and supping out; at clubs, at routs, at theatres; he is a guest with Johnson at the Thrales', and an object of Mrs. Thrale's lively sallies; he is a lion at Mrs. Vesey's and Mrs. Montagu's, where some of the high-bred blue-stockings pronounce him a "wild genius," and others, peradventure, a "wild Irishman." In the meantime his pecuniary difficulties are increasing upon him, conflicting with his proneness to pleasure and expense, and contributing by the harassment of his mind to the wear and tear of his constitution. His "Animated Nature," though not finished, has been

entirely paid for, and the money spent. The money advanced by Garrick on Newbery's note still hangs over him as a debt. The tale on which Newbery had loaned from two to three hundred pounds previous to the excursion to Barton has proved a failure. The bookseller is urgent for the settlement of his complicated account; the perplexed author has nothing to offer him in liquidation but the copyright of the comedy which he has in his portfolio; "Though to tell you the truth, Frank," said he, "there are great doubts of its success." The offer was accepted, and, like bargains wrung from Goldsmith in times of emergency, turned out a golden speculation to the bookseller.

In this way Goldsmith went on "overrunning the constable," as he termed it; spending everything in advance; working with an overtasked head and weary heart to pay for past pleasure and past extravagance, and at the same time incurring new debts, to perpetuate his struggles and darken his future prospects. While the excitement of society and the excitement of composition conspire to keep up a feverishness of the system, he has incurred an unfortunate habit of quacking himself with James's powders, a fashionable panacea of the day.

A farce produced this year by Garrick, and entitled "The Irish Widow," perpetuates the memory of practical jokes played off a year or two previously upon the alleged vanity of poor simple-hearted Goldsmith. He was one evening at the house of his friend Burke, when he was beset by a tenth muse, an Irish widow and authoress, just arrived from Ireland, full of brogue and blunders, and poetic fire and rantipole gentility. She was soliciting subscriptions for her poems, and assailed Goldsmith for his patronage—the great Goldsmith, her countryman, and of course her friend. She overpowered him with eulogiums on his own poems, and then read some of her own with vehemence of tone and gesture, appealing continually to the great Goldsmith to know how he relished them.

Poor Goldsmith did all that a kind-hearted and gallant gentleman could do in such a case; he praised her poems as far as the stomach of his sense would permit—perhaps a little further; he offered her his subscription, and it was not until she had retired with many parting compliments to poor Goldsmith, that he pronounced the poetry that had been inflicted on him execrable. The whole scene had been a hoax got up by Burke for the amusement of his company, and the Irish widow, so admirably performed, had been personated by a Mrs. Balfour, a lady of his connexion, of great sprightliness and talent.

We see nothing in the story to establish the alleged vanity of Goldsmith, but we think it tells rather to the disadvantage of Burke—being unwarrantable under their relations of friendship, and a species of wagery quite beneath his genius.

Croker, in his notes to Boswell, gives another of these practical jokes perpetrated by Burke at the expense of Goldsmith's credulity. It was related to Croker by Colonel O'Moore, of Cloghan Castle, in Ireland, who was a party concerned. The Colonel and Burke, walking one day through Leicester-square on their way to Sir Joshua Reynolds's, with whom they were to dine, observed Goldsmith, who was likewise to be a guest, standing and regarding a crowd which was staring and shouting at some foreign ladies in the window of an hotel. "Observe Goldsmith," said Burke to O'Moore, "and mark what passes between us at Sir Joshua's." They passed on and reached there before him. Burke received Goldsmith with affected reserve and coldness; being pressed to explain the reason, "Really," said he, "I am ashamed to keep company with a person who could act as you have just done in the Square." Goldsmith protested that he was ignorant of what was meant. "Why," said Burke, "did you not exclaim as you were looking up at those women, what stupid beasts the crowd must

be for staring with such admiration at those *painted Jzebels*, while a man of your talents passed by unnoticed?" "Surely, surely, my dear friend," cried Goldsmith, with alarm—"surely I did not say so?" "Nay," replied Burke, "if you had not said so, how should I have known it?" "That's true," answered Goldsmith, "I am very sorry—it was very foolish; *I do recollect that something of the kind passed through my mind, but I did not think I had uttered it.*"

It is proper to observe that these jokes were played off by Burke before he had attained the full eminence of his social position, and that he may have felt privileged to take liberties with Goldsmith as his countryman and college associate. It is evident, however, that the peculiarities of the latter, and his guileless simplicity, made him a butt for the broad waggonery of some of his associates; while others more polished, though equally perfidious, were on the watch to give currency to his bulls and blunders.

The Stratford jubilee, in honour of Shakspeare, where Boswell had made a fool of himself, was still in every one's mind. It was sportively suggested that a fête should be held at Lichfield in honour of Johnson and Garrick, and that the "Beaux' Stratagem" should be played by the members of the Literary Club. "Then," exclaimed Goldsmith, "I shall certainly play Scrub. I should like of all things to try my hand at that character." The unwary speech, which any one else might have made without comment, has been thought worthy of record as whimsically characteristic. Beauclerc was extremely apt to circulate anecdotes at his expense, founded, perhaps, on some trivial incident, but dressed up with the embellishments of his sarcastic brain. One relates to a venerable dish of peas, served up at Sir Joshua's table, which should have been green, but were any other colour. A wag suggested to Goldsmith, in a whisper, that they should be sent to Hammersmith, as that was the way to *turn 'em green* (Turnham-green). Goldsmith, delighted with the pun, endeavoured to repeat it at Burke's table, but missed his point. "That is the way to *make 'em green*," said he. Nobody laughed. He perceived he was at fault. "I mean that is the road to *turn 'em green*." A dead pause and a stare; "whereupon," adds Beauclerc, "he started up disconcerted, and abruptly left the table." This is evidently one of Beauclerc's caricatures.

On another occasion the poet and Beauclerc were seated at the theatre next to Lord Shelburne, the minister, whom political writers thought proper to nickname Malagrida. "Do you know," said Goldsmith to his lordship, in the course of conversation, "that I never could conceive why they call you Malagrida, *for* Malagrida was a very good sort of man." This was too good a trip of the tongue for Beauclerc to let pass: he serves it up in his next letter to Lord Charlemont, as a specimen of a mode of turning a thought the wrong way peculiar to the poet; he makes merry over it with his witty and sarcastic compeer, Horace Walpole, who pronounces it "a picture of Goldsmith's whole life." Dr. Johnson alone, when he hears it bandied about as Goldsmith's last blunder, growls forth a friendly defence; "Sir," said he, "it was a mere blunder in emphasis. He meant to say, I wonder they should use Malagrida as a term of reproach." Poor Goldsmith! On such points he was ever doomed to be misinterpreted. Rogers, the poet, meeting in times long subsequent with a survivor from those days, asked him what Goldsmith really was in conversation. The old conversational character was too deeply stamped in the memory of the veteran to be effaced. "Sir," replied the old wiseacre, "*he was a fool.*" The right word never came to him. If you gave him back a bad shilling, he'd say, Why its as good a shilling as ever was *born*. You know he ought to have said *coined*. *Coined*, sir, never entered his head. *He was a fool, sir.*"

We have so many anecdotes in which Goldsmith's simplicity is played upon, that it is quite a treat to meet with one in which he is represented playing upon the simplicity of others, especially when the victim of his joke is the "Great Cham" himself, whom all others are disposed to hold so much in awe. Goldsmith and Johnson were supping cosily together at a tavern in Dean-street, Soho, kept by Jack Roberts, a singer at Drury-lane, and a protégé of Garrick's. Johnson delighted in these gastronomical "tête-à-têtes," and was expatiating in high good humour on a dish of rumps and kidneys, the veins of his forehead swelling with the ardour of mastication. "These," said he, "are pretty little things; but a man must eat a great many of them before he is filled." "Aye; but how many of them," asked Goldsmith, with affected simplicity, "would reach to the moon?" "To the moon! Ah, sir, that I fear exceeds your calculation." "Not at all, sir; I think I could tell." "Pray, then, sir, let us hear." "Why, sir, one, *if it were long enough!*" Johnson growled for a time at finding himself caught in such a trite school-boy trap. "Well, sir," cried he at length, "I have deserved it. I should not have provoked so foolish an answer by so foolish a question."

Among the many incidents related as illustrative of Goldsmith's vanity and envy is one which occurred one evening when he was in a drawing-room with a party of ladies, and a ballad-singer under the window struck up his favourite song of "Sally Salisbury." "How miserably this woman sings!" exclaimed he. "Pray, doctor," said the lady of the house, "could you do it better?" "Yes, madam, and the company shall be judges." The company, of course, prepared to be entertained by an absurdity; but their smiles were well nigh brought to tears, for he acquitted himself with a skill and pathos that drew universal applause. He had, in fact, a delicate ear for music, which had been jarred by the false notes of the ballad-singer; and there were certain pathetic ballads, associated with recollections of his childhood, which were sure to touch the springs of his heart. We have another story of him, connected with ballad-singing, which is still more characteristic. He was one evening at the house of Sir William Chambers, in Berners-street, seated at a whist-table with Sir William, Lady Chambers, and Baretti, when all at once he threw down his cards, hurried out of the room, and into the street. He returned in an instant, resumed his seat, and the game went on. Sir William, after a little hesitation, ventured to ask the cause of his retreat, fearing he had been overcome by the heat of the room. "Not at all," replied Goldsmith; "but in truth I could not bear to hear that unfortunate woman in the street, half singing, half sobbing, for such tones could only arise from the extremity of distress; her voice grated painfully on my ear and jarred my frame, so that I could not rest until I had sent her away." It was, in fact, a poor ballad-singer, whose cracked voice had been heard by others of the party, but without having the same effect on their sensibilities. It was the reality of his fictitious scene in the story of the Man in Black; wherein he describes a woman in rags, with one child in her arms and another on her back, attempting to sing ballads, but with such a mournful voice that it was difficult to determine whether she was singing or crying. "A wretch," he adds, "who, in the deepest distress, still aimed at good humour, was an object my friend was by no means capable of withstanding." The Man in Black gave the poor woman all that he had—a bundle of matches. Goldsmith, it is probable, sent his ballad-singer away rejoicing, with all the money he had in his pocket.

Ranelagh was at that time greatly in vogue as a place of public entertainment. It was situated near Chelsea; the principal room was a Rotunda of great dimensions, with an orchestra in the centre, and tiers of boxes all

round. It was a place to which Johnson resorted occasionally. "I am a great friend to public amusements," said he, "for they keep people from vice."\* Goldsmith was equally a friend to them, though perhaps not altogether on such moral grounds. He was particularly fond of masquerades, which were then exceedingly popular, and got up at Ranelagh with great expense and magnificence. Sir Joshua Reynolds, who had likewise a taste for such amusements, was sometimes his companion, at other times he went alone; his peculiarities of person and manner would soon betray him, whatever might be his disguise, and he would be singled out by wags acquainted with his foibles, and more successful than himself in maintaining their incognito, as a capital subject to be played upon. Some, pretending not to know him, would decry his writings, and praise those of his contemporaries; others would laud his verses to the skies, but purposely misquote and burlesque them; others would annoy him with parodies; while one young lady, whom he was teasing, as he supposed, with great success and infinite humour, silenced his rather boastful laughter by quoting his own line about "the loud laugh that speaks the vacant mind." On one occasion he was absolutely driven out of the house by the persevering jokes of a wag, whose complete disguise gave him no means of retaliation.

His name appearing in the newspapers among the distinguished persons present at one of these amusements, his old enemy, Kenrick, immediately addressed to him a copy of anonymous verses, to the following purport:—

*"To Dr. Goldsmith, on seeing his name in the list of mumm-  
mers at the late masquerade:—"*

How widely different, Goldsmith, are the ways  
Of Doctors now and those of ancient days!  
Theirs taught the truth in academic shades—  
Ours in lewd hops and midnight masquerades.  
So changed the times! say, philosophic sage,  
Whose genius suits so well this tasteful age,  
Is the Pantheon, late a sink obscene,  
Become the fountain of chaste Hippocrene?  
Or do thy moral numbers quainly flow,  
Inspired by th' "Aganippe" of Soho?  
Do wisdom's sons gorge dates and vermicelli,  
Like beastly Bickerstaff or boistering Kelly?  
Or art thou tired of th' undeserved applause,  
Bestow'd on bards affecting Virtue's cause?  
Is this the good that makes the humble vain—  
The good philosophy should not disdain?  
If so, let pride dissemble all it can,  
A modern sage is still much less than man.

Goldsmith was keenly sensitive to attacks of the kind, and, meeting Kenrick at the Chapter Coffee-house, called him to sharp account for taking such a liberty with his name, and calling his morals in question, merely on account of his being seen at a place of general resort and amusement. Kenrick shuffled and sneaked, protesting that he meant nothing derogatory to his private character. Goldsmith let him know, however, that he was aware of his having more than once indulged in attacks of this dastard kind, and intimated that another such outrage would be followed by personal chastisement.

Kenrick, having played the craven in his presence, avenged himself as soon as he was gone by complaining of his having made a wanton attack upon him, and by making coarse comments upon his writings, conversation, and person.

\* "Alas, sir!" said Johnson, speaking, when in another mood, of grand houses, fine gardens, and splendid places of public amusement; "alas, sir! these are only struggles for happiness. When I first entered Ranelagh, it gave an expansion and gay sensation to my mind such as I never experienced anywhere else. But, as Xerxes wept when he viewed his immense army, and considered that not one of that great multitude would be alive a hundred years afterwards, so it went to my heart to consider that there was not one in all that brilliant circle that was not afraid to go home and think."

The scurrilous satire of Kenrick, however unmerited, may have checked Goldsmith's taste for masquerades. Sir Joshua Reynolds calling on the poet one morning, found him walking about his room in somewhat of a reverie, kicking a bundle of clothes before him like a foot-ball. It proved to be an expensive masquerade dress, which he said he had been fool enough to purchase, and as there was no other way of getting the worth of his money, he was trying to take it out in exercise.

## CHAP. XXXVI.

Invitation to Christmas—The spring-velvet coat—The haymaking wig—The mischances of loo—The fair culprit—A dance with the Jessamy Bride.

From the feverish dissipations of town, Goldsmith is summoned away to partake of the genial dissipations of the country. In the month of December, a letter from Mrs. Bunbury invites him down to Barton to pass the Christmas holidays. The letter is written in the usual playful vein which marks his intercourse with this charming family. He is to come in his "smart spring-velvet coat," to bring a new wig to dance with the haymakers in, and above all, to follow the advice of herself and her sister (the Jessamy Bride) in playing loo. This letter, which plays so archly, yet kindly, with some of poor Goldsmith's peculiarities, and bespeaks such real ladylike regard for him, requires a word or two of annotation. The spring-velvet suit alluded to appears to have been a gallant adornment (somewhat in the style of the famous bloom-coloured coat) in which Goldsmith had figured in the preceding month of May—the season of blossoms—for, on the 21st of that month, we find the following entry in the chronicle of Mr. William Filby, tailor:—"To your blue velvet suit, £21 10s. 9d." Also, about the same time, a suit of livery and a crimson collar for the serving man. Again we hold the Jessamy Bride responsible for this gorgeous splendour of wardrobe.

The new wig, no doubt, is a bag-wig and solitaire, still highly the mode, and in which Goldsmith is represented as figuring when in full dress, equipped with his sword.

As to the dancing with the haymakers, we presume it alludes to some gambol of the poet in the course of his former visit to Barton, when he ranged the fields and lawns a chartered libertine, and tumbled into the fish-ponds.

As to the suggestions about loo, they are in sportive allusion to the doctor's mode of playing that game in their merry evening parties—affecting the desperate gambler and easy dupe—running counter to all rule—making extravagant ventures—reproaching all others with cowardice—dashing at all hazards at the pool, and getting himself completely loo'd, to the great amusement of the company. The drift of the fair sisters' advice was most probably to tempt him on, and then leave him in the lurch.

With these comments we subjoin Goldsmith's reply to Mrs. Bunbury, a fine piece of off-hand humorous writing, which has but in late years been given to the public, and which throws a familiar light on the social circle at Barton.

"Madam,—I read your letter with all that allowance which critical candour could require, but after all find so much to object to, and so much to raise my indignation, that I cannot help giving it a serious answer.—I am not so ignorant, madam, as not to see there are many sarcasms contained in it, and solecisms also. (Solecism is a word that comes from the town of Solcis in Attica, among the Greeks, built by Solon, and applied as we use the word Kidderminster for curtains from a town also of that name—but this is learning you

have no taste for!—I say, madam, there are many sarcasms in it, and solecisms also. But not to seem an ill-natured critic, I'll take leave to quote your own words, and give you my remarks upon them as they occur. You begin as follows:—

I hope, my good Doctor, you soon will be here,  
And your spring-velvet coat very smart will appear.  
To open our ball the first day of the year.

"Pray, madam, where did you ever find the epithet 'good' applied to the title of doctor? Had you called me 'learned doctor,' or 'grave doctor,' or 'noble doctor,' it might be allowable, because they belong to the profession. But, not to cavil at trifles, you talk of my 'spring-velvet coat,' and advise me to wear it the first day in the year, that is, in the middle of winter!—a spring-velvet coat in the middle of winter!!! That would be a solecism indeed! and yet, to increase the inconsistency, in another part of your letter you call me a beau. Now, on one side or other you must be wrong. If I am a beau, I can never think of wearing a spring-velvet in winter; and if I am not a beau, why, then, that explains itself. But let me go on to your two next strange lines.—

And bring with you a wig, that is modish and gay,  
To dance with the girls that are makers of hay.

"The absurdity of making hay at Christmas you yourself seem sensible of: you say your sister will laugh; and so indeed she well may! The Latins have an expression for a contemptuous kind of laughter, '*naso contemnere adunco*'; that is, to laugh with a crooked nose. She may laugh at you in the manner of the ancients if she thinks fit. But now I come to the most extraordinary of all extraordinary propositions, which is, to take your and your sister's advice in playing at loo. The presumption of the offer raises my indignation beyond the bounds of prose; it inspires me at once with verse and resentment. I take advice? and from whom? You shall hear:—

First let me suppose, what may shortly be true,  
The company set, and the word to be Loo:  
All smirking, and pleasant, and big with adventure,  
And ogling the stake which is fix'd in the centre.  
Round and round go the stakes, while I inwardly damn  
At never once finding a visit from Pam.  
I lay down my stake, apparently cool,  
While the harpies about me all pocket the pool.  
I fret in my gizzard, yet, cautious and sly,  
I wish all my friends may be bolder than I:  
Yet still they sit snug, not a creature will aim  
By losing their money to venture at fame.  
'Tis in vain that at niggardly caution I scold,  
'Tis in vain that I flatter the brave and the bold:  
All play their own way, and they think me an ass—  
'What does Mrs. Bunbury?'—'I, sir? I pass.'  
'Pray what does Miss Horneck? take courage, come, do.'  
'Who, I? let me see, sir, why I must pass too.'  
Mr. Bunbury frets, and I fret like the devil,  
To see them so cowardly, lucky, and civil.  
Yet still I sit snug, and continue to sigh on,  
Till, made by my losses as bold as a lion,  
I venture at all, while my avarice regards  
The whole pool as my own—"Come, give me five cards."  
'Well done!' cry the ladies. 'Ah, Doctor, that's good!  
The pool's very rich—ah! the Doctor is loo'd!  
Thus foil'd in my courage, on all sides perplex,  
I ask for advice from the lady that's next:  
'Pray, ma'am, be so good as to give your advice;  
Don't you think the best way is to venture for't twice?'  
'I advise,' cries the lady, 'to try it, I own—'  
'Ah! the Doctor is loo'd! Come, Doctor, put down.'  
Thus, playing, and playing, I still grow more eager,  
And so bold, and so bold, I'm at last a bold beggar.  
Now, ladies, I ask, if law matters you're skill'd in,  
Whether crimes such as yours should not come before Fielding:  
For giving advice that is not worth a straw,  
May well be call'd picking of pockets in law;  
And picking of pockets, with which I now charge ye,  
Is, by quintto Elizabeth, Death without Clergy.  
What justice, when both to the Old Bailey brought!  
By the gods, I'll enjoy it, though 'tis but in thought!

Both are placed at the bar, with all proper decorum,  
With bunches of fennel, and nosegays before 'em;  
Both cover their faces with mobs and all that,  
But the judge bids them, angrily, take off their hat.  
When uncover'd, a buzz of inquiry runs round,  
'Pray what are their crimes?'—'They've been pilfering found.'  
'But pray what have they pilfer'd?'—'A doctor, I hear.'  
'What, yon solemn-faced, odd-looking man that stands near?'  
'The same.'—'What a pity! how does it surprise one,  
Two handsomer culprits I never set eyes on!  
Then their friends all come round me with cringing and leering,  
To melt me to pity, and soften my swearing.  
First Sir Charles advances, with phrases well-strung—  
'Consider, dear Doctor, the girls are but young.'  
'The younger the worse,' I return him again,  
'It shows that their habits are all dyed in grain.'  
'But then they're so handsome, one's bosom it grieves.'  
'What signifies handsome, when people are thieves.'  
'But where is your justice? their cases are hard.'  
'What signifies justice? I want the reward.'

"There's the parish of Edmonton offers forty pounds;  
there's the parish of St. Leonard, Shoreditch, offers  
forty pounds; there's the parish of Tyburn, from the  
Hog in-the-pound to St. Giles's watch-house, offers forty  
pounds. I shall have all that if I convict them!—

'But consider their case—it may yet be your own!  
And see how they kneel! Is your heart made of stone?'  
This moves: so at last I agree to relent,  
For ten pounds in hand, and ten pounds to be spent.

"I challenge you all to answer this: I tell you, you  
cannot. It cuts deep. But now for the rest of the letter:  
and next—but I want room—so I believe I shall battle  
the rest out at Barton some day next week—I don't  
value you all? "O. G."

We regret that we have no record of this Christmas  
visit to Barton—that the poet had no Boswell to follow  
at his heels, and take notes of all his sayings and doings.  
We can only picture him in our minds, casting off all  
care—enacting the lord of misrule—presiding at the  
Christmas revels—providing all kinds of merriment—  
keeping the card-table in an uproar, and finally opening  
the ball on the first day of the year in his spring-velvet  
suit, with the Jessamy Bride for a partner.

## CHAP. XXXVII.

Theatrical delays—Negotiations with Colman—Letter to Garrick—  
Croaking of the manager—Naming of the play—"She Stoops  
to Conquer"—Foot's primitive puppet-show, "Piety on  
Pattens"—First performance of the comedy—Agitation of  
the author—Success—Colman squibbed out of town.

The gay life depicted in the two last chapters, while it  
kept Goldsmith in a state of continual excitement,  
aggravated the malady which was impairing his con-  
stitution; yet his increasing perplexities in money  
matters drove him to the dissipation of society as a  
relief from solitary care. The delays of the theatre  
added to those perplexities. He had long since finished  
his new comedy, yet the year 1772 passed away without  
his being able to get it on the stage. No one, unin-  
tiated in the interior of a theatre, that little world of  
traps and trickery, can have any idea of the obstacles  
and perplexities multiplied in the way of the most  
eminent and successful author by the mismanagement  
of managers, the jealousies and intrigues of rival authors,  
and the fantastic and impertinent caprices of actors. A  
long and baffling negotiation was carried on between  
Goldsmith and Colman, the manager of Covent Garden,  
who retained the play in his hands until the middle  
of January (1773) without coming to a decision. The  
theatrical season was rapidly passing away, and Gold-  
smith's pecuniary difficulties were augmenting and  
pressing on him. We may judge of his anxiety by the  
following letter:—

"To George Colman, Esq.

"DEAR SIR,—I entreat you'll relieve me from that state of suspense in which I have been kept for a long time. Whatever objections you have made or shall make to my play, I will endeavour to remove and not argue about them. To bring in any new judges either of its merits or faults I can never submit to. Upon a former occasion, when my other play was before Mr. Garrick, he offered to bring me before Mr. Whitehead's tribunal, but I refused the proposal with indignation: I hope I shall not receive as harsh treatment from you as from him. I have, as you know, a large sum of money to make up shortly; by accepting my play, I can readily satisfy my creditor that way; at any rate, I must look to some certainty to be prepared. For God's sake take the play, and let us make the best of it, and let me have the same measure, at least, which you have given as bad plays as mine.

"I am, your friend and servant,

"OLIVER GOLDSMITH."

Colman returned the manuscript, with the blank sides of the leaves scored with disparaging comments and suggested alterations, but with the intimation that the faith of the theatre should be kept, and the play acted notwithstanding. Goldsmith submitted the criticisms to some of his friends, who pronounced them trivial, unfair, and contemptible, and intimated that Colman, being a dramatic writer himself, might be actuated by jealousy. The play was then sent, with Colman's comments written on it, to Garrick; but he had scarce sent it when Johnson interfered, represented the evil that might result from an apparent rejection of it by Covent Garden, and undertook to go forthwith to Colman and have a talk with him on the subject. Goldsmith, therefore, penned the following note to Garrick:—

"DEAR SIR,—I ask many pardons for the trouble I gave you yesterday. Upon more mature deliberation, and the advice of a sensible friend, I began to think it indelicate in me to throw upon you the odium of confirming Mr. Colman's sentence. I therefore request you will send my play back by my servant; for having been assured of having it acted at the other house, though I confess yours in every respect more to my wish, yet it would be folly in me to undergo an advantage which lies in my power, of appealing from Mr. Colman's opinion to the judgment of the town. I entreat, if not too late, you will keep this affair a secret for some time.

"I am, dear sir, your very humble servant,

"OLIVER GOLDSMITH."

The negotiation of Johnson with the manager of Covent Garden was effective. "Colman," he says, "was prevailed on at last, by much solicitation, nay a kind of force," to bring forward the comedy. Still the manager was ungenerous—or, at least, indiscreet enough to express his opinion that it would not reach a second representation. The plot, he said, was bad, and the interest not sustained; "it dwindled, and dwindled, and at last went out like the snuff of a candle." The effect of his croaking was soon apparent within the walls of the theatre. Two of the most popular actors, Woodward and Gentleman Smith, to whom the parts of Tony Lumpkin and Young Marlow were assigned, refused to act them—one of them alleging, in excuse, the evil predictions of the manager. Goldsmith was advised to postpone the performance of his play until he could get these important parts well supplied. "No," said he, "I would sooner that my play were damned by bad players than merely saved by good acting."

Quick was substituted for Woodward in Tony Lumpkin, and Lee Lewis, the harlequin of the theatre, for Gentleman Smith in Young Marlow; and both did justice to their parts.

Great interest was taken by Goldsmith's friends in the success of his piece. The rehearsals were attended

by Johnson, Cradock, Murphy, Reynolds and his sister, and the whole Horneck connexion, including, of course, the *Jessamy Bride*, whose presence may have contributed to flutter the anxious heart of the author. The rehearsals went off with great applause; but that Colman attributed to the partiality of friends. He continued to croak, and refused to risk any expense in new scenery or dresses on a play which he was sure would prove a failure.

The time was at hand for the first representation, and as yet the comedy was without a title. "We are all in labour for a name for Goldy's play," said Johnson, who, as usual, took a kind of fatherly protecting interest in poor Goldsmith's affairs. "The Old House a New Inn" was thought of for a time, but still did not please. Sir Joshua Reynolds proposed "The Belle's Stratagem," an elegant title, but not considered applicable, the perplexities of the comedy being produced by the mistake of the hero, not the stratagem of the heroine. The name was afterwards adopted by Mrs. Cowley for one of her comedies. "The Mistakes of a Night" was the title at length fixed upon, to which Goldsmith prefixed the words, "She Stoops to Conquer."

The evil bodings of Colman still continued: they were even communicated in the box-office to the servant of the Duke of Gloucester, who was sent to engage a box. Never did the play of a popular writer struggle into existence through more difficulties.

In the meantime Foote's "Primitive Puppet-show," entitled "The Handsome Housemaid, or Piety on Patens," had been brought out at the Haymarket on the 15th of February. All the world, fashionable and unfashionable, had crowded to the theatre. The street thronged with equipages—the doors were stormed by the mob. The burlesque was completely successful, and sentimental comedy received its quietus. Even Garrick, who had recently befriended it, now gave it a kick, as he saw it going down hill, and sent Goldsmith a humorous prologue to help his comedy of the opposite school. Garrick and Goldsmith, however, were now on very cordial terms, to which the social meetings in the circle of the Hornecks and Bunburys may have contributed.

On the 15th of March the new comedy was to be performed. Those who had stood up for its merits, and been irritated and disgusted by the treatment it had received from the manager, determined to muster their forces, and aid in giving it a good launch upon the town. The particulars of this confederation, and of its triumphant success, are amusingly told by Cumberland in his Memoirs.

"We were not over sanguine of success, but perfectly determined to struggle hard for our author. We accordingly assembled our strength at the Shakespeare Tavern, in a considerable body, for an early dinner, where Samuel Johnson took the chair at the head of a long table, and was the life and soul of the corps: the poet took post silently by his side, with the Burkes, Sir Joshua Reynolds, Fitzherbert, Caleb Whitefoord, and a phalanx of North British predetermined applauders, under the banner of Major Mills, all good men and true. Our illustrious president was in inimitable glee; and poor Goldsmith that day took all his raillery as patiently and complacently as my friend Boswell would have done any day or every day of his life. In the meantime we did not forget our duty, and though we had a better comedy going, in which Johnson was chief actor, we betook ourselves in good time to our separate and allotted posts, and waited the awful drawing up of the curtain. As our stations were preconcocted, so were our signals for plaudits arranged and determined upon, in a manner that gave every one his cue where to look for them, and how to follow them up.

"We had among us a very worthy and efficient member, long since lost to his friends and the world at large,

Adam Drummond, of amiable memory, who was gifted by nature with the most sonorous, and at the same time the most contagious, laugh that ever echoed from the human lungs. The neighing of the horse of the son of Hystaspes was a whisper to it—the whole thunder of the theatre could not drown it. This kind and ingenious friend fairly forewarned us that he knew no more when to give his fire than the cannon did that was planted on the battery. He desired, therefore, to have a flapper at his elbow, and I had the honour to be deputed to that office. I planted him in an upper box, pretty nearly over the stage, in full view of the pit and galleries, and perfectly well situated to give the echo all its play through the hollows and recesses of the theatre. The success of our manœuvre was complete. All eyes were upon Johnson, who sat in a front row of a side box; and when he laughed, everybody thought themselves warranted to roar. In the meantime, my friend followed signals with a rattle so irresistibly comic, that, when he had repeated it several times, the attention of the spectators was so engrossed by his person and performances, that the progress of the play seemed likely to become a secondary object, and I found it prudent to insinuate to him that he might halt his music without any prejudice to the author; but, alas! it was now too late to rein him in; he had laughed upon my signal where he found no joke, and now, unluckily, he fancied that he found a joke in almost everything that was said, so that nothing in nature could be more mal-apropos than some of his bursts every now and then were. These were dangerous moments, for the pit began to take umbrage; but we carried our point through, and triumphed, not only over Colman's judgment, but our own."

Much of this statement has been condemned as exaggerated or discoloured. Cumberland's memoirs have generally been characterised as partaking of romance, and in the present instance he had particular motives for tampering with the truth. He was a dramatic writer himself, jealous of the success of a rival, and anxious to have it attributed to the private management of friends. According to various accounts, public and private, such management was unnecessary, for the piece was "received throughout with the greatest acclamations."

Goldsmith, in the present instance, had not dared, as on a former occasion, to be present at the first performance. He had been so overcome by his apprehensions, that, at the preparatory dinner, he could hardly utter a word, and was so choked that he could not swallow a mouthful. When his friends trooped to the theatre, he stole away to St James's Park: there he was found by a friend, between seven and eight o'clock, wandering up and down the Mall like a troubled spirit. With difficulty he was persuaded to go to the theatre, where his presence might be important should any alteration be necessary. He arrived at the opening of the fifth act, and made his way behind the scenes. Just as he entered there was a slight hiss, at the improbability of Tony Lumpkin's trick on his mother, in persuading her she was forty miles off, on Crackskull Common, though she had been trundled about on her own grounds. "What's that? What's that?" cried Goldsmith to the manager, in great agitation. "Pshaw! Doctor," replied Colman, sarcastically, "don't be frightened at a squib, when we've been sitting these two hours on a barrel of gunpowder!" Though of a most forgiving nature, Goldsmith did not easily forget this ungracious and ill timed sally.

If Colman was, indeed, actuated by the paltry motives ascribed to him in his treatment of this play, he was most amply punished by its success, and by the taunts, epigrams, and censures levelled at him through the press, in which his false prophecies were jeered at, his critical judgment called in question, and he was openly taxed with literary jealousy. So galling and unrelenting

was the fire, that he at length wrote to Goldsmith, entreating him "to take him off the rack of the newspapers;" in the meantime, to escape the laugh that was raised about him in the theatrical world of London, he took refuge in Bath during the triumphant career of the comedy.

The following is one of the many squibs which assailed the ears of the manager:—

*"To George Colman, Esq.*

ON THE SUCCESS OF DR. GOLDSMITH'S NEW COMEDY.

Come, Coley, doff those mourning weeds,  
Nor thus with jokes be flamm'd;  
Tho' Goldsmith's present play succeeds,  
The next may still be damn'd.  
As this has 'scaped without a fall,  
To sink his next prepare;  
New actors hire from Wapping Wall,  
And dresses from Rag Fair.  
For scenes let tatter'd blankets fly,  
The prologue Kelly write;  
Then swear again the piece must die  
Before the author's sight.  
Should these tricks fail, the lucky elf,  
To bring to lasting shame,  
E'en write the best you can yourself,  
And print it in his name."

The solitary hiss, which had startled Goldsmith, was ascribed by some of the newspaper scribblers to Cumberland himself, who was "manifestly miserable" at the delight of the audience, or to Ossian Macpherson, who was hostile to the whole Johnson clique, or to Goldsmith's rival, Kelly. The following is one of his epigrams which appeared:—

At Dr. Goldsmith's merry play,  
All the spectators laugh, they say,  
The assertion, sir, I must deny,  
For Cumberland and Kelly cry.

Another, addressed to Goldsmith, alludes to Kelly's early apprenticeship to stay-making:—

If Kelly finds fault with the "shape" of your muse,  
And thinks that too loosely it plays,  
He surely, dear Doctor, will never refuse  
To make it a new pair of Stays!"

Cradock had returned to the country before the production of the play; the following letter, written just after the performance, gives an additional picture of the thorns which beset an author in the path of theatrical literature:—

"MY DEAR SIR,—The play has met with a success much beyond your expectations or mine. I thank you sincerely for your epilogue, which, however, could not be used, but with your permission shall be printed. The story, in short, is this. Murphy sent me rather the outline of an epilogue, which was to be sung by Miss Catley, and which she approved; Mrs. Bulkley, hearing this, insisted on throwing up her part (Miss Hardcastle) unless, according to the custom of the theatre, she were permitted to speak the epilogue. In this embarrassment, I thought of making a quarrelling epilogue between Catley and her, debating *who* should speak the epilogue; but then Miss Catley refused, after I had taken the trouble of drawing it out. I was then at a loss indeed; an epilogue was to be made, and for none but Mrs. Bulkley. I made one, and Colman thought it too bad to be spoken; I was obliged, therefore, to try a fourth time, and I made a very mawkish thing, as you will shortly see. Such is the history of my stage adventures, and which I have at last done with. I cannot help saying that I am very sick of the stage; and though I believe I shall get three terrible benefits, yet I shall, on the whole, be a loser, even in a pecuniary light: my ease and comfort I certainly lost while it was in agitation.

"I am, my dear Cradock,

"Your obliged and obedient servant,

"OLIVER GOLDSMITH."

"P.S.—Present my most humble respects to Mrs. Cradock."

Johnson, who had taken such a conspicuous part in promoting the interests of poor "Goldy," was triumphant at the success of the piece. "I know of no comedy for many years," said he, "that has so much exhilarated an audience; that has answered so much the great end of comedy—in making an audience merry."

Goldsmith was happy also in gaining applause from less authoritative sources. Northcote, the painter, then a youthful pupil of Sir Joshua Reynolds, and Ralph, Sir Joshua's confidential man, had taken their stations in the gallery to lead the applause in that quarter. Goldsmith asked Northcote's opinion of the play. The youth modestly declared he could not presume to judge in such matters. "Did it make you laugh?" "Oh, exceedingly!" "That is all I require," replied Goldsmith; and rewarded him for his criticism by box-tickets for his first benefit night.

The comedy was immediately put to press, and dedicated to Johnson in the following grateful and affectionate terms:—

"In inscribing this slight performance to you, I do not mean so much to compliment you as myself. It may do me some honour to inform the public, that I have lived many years in intimacy with you. It may serve the interests of mankind, also, to inform them, that the greatest wit may be found in a character, without impairing the most unaffected piety."

The copyright was transferred to Mr. Newbery, according to agreement, whose profits on the sale of the work far exceeded the debts for which the author in his perplexities had pre-engaged it. The sum which accrued to Goldsmith from his benefit nights afforded but a slight palliation of his pecuniary difficulties. His friends, while they exulted in his success, little knew of his continually increasing embarrassments, and of the anxiety of mind which kept tasking his pen, while it impaired the ease and freedom of spirit necessary to felicitous composition.

#### CHAP. XXXVIII.

A newspaper attack—The Evans affray—Johnson's comment.

The triumphant success of "She Stoops to Conquer" brought forth, of course, those carplings and cavillings of underling scribblers which are the thorns and briars in the path of successful authors. Goldsmith, though easily nettled by attacks of the kind, was at present too well satisfied with the reception of his comedy to heed them; but the following anonymous letter, which appeared in a public paper, was not to be taken with equal equanimity:—

"For the *London Packet*.—To Dr. Goldsmith.

*Vous vous noyez par vanité.*

"SIR,—The happy knack which you have learned of puffing your own compositions provokes me to come forth. You have not been the editor of newspapers and magazines not to discover the trick of literary *humbug*; but the gauze is so thin that the very foolish part of the world see through it, and discover the doctor's monkey face and cloven foot. Your poetic vanity is as unpardonable as your personal. Would man believe it, and will woman bear it, to be told that for hours the great Goldsmith will stand surveying his grotesque ouran-outang figure in a pier-glass? Was but the lovely H—k as much enamoured, you would not sigh, my gentle swain, in vain. But your vanity is preposterous. How will this same bard of Bedlam ring the changes in the praise of Goldy? But what has he to be either proud or vain of? 'The Traveller' is a flimsy poem, built upon false principles—principles diametrically opposite to liberty.

What is the 'Good-natured Man' but a poor water-gruel dramatic dose? What is 'The Deserted Village,' but a pretty poem of easy numbers, without fancy, dignity, genius, or fire? And pray what may be the last *speaking pantomime*, so praised by the doctor himself, but an incoherent piece of stuff, the figure of a woman with a fish's tail, without plot, incident, or intrigue? We are made to laugh at stale, dull jokes, wherein we mistake pleasantry for wit, and grimace for humour—wherein every scene is unnatural, and inconsistent with the rules, the laws, of nature and of the drama; viz., two gentlemen come to a man of fortune's house, eat, drink, &c., and take it for an inn. The one is intended as a lover for the daughter; he talks with her for some hours, and, when he sees her again in a different dress, he treats her as a bar-girl, and swears she squinted. He abuses the master of the house, and threatens to kick him out of his own doors. The squire, whom we are told is to be a fool, proves to be the most sensible being of the piece; and he makes out a whole act by bidding his mother lie close behind a bush, persuading her that his father, her own husband, is a highwayman, and that he has come to cut their throats; and to give his cousin an opportunity to go off, he drives his mother over hedges, ditches, and through ponds. There is not, sweet, sucking Johnson, a natural stroke in the whole play but the young fellow's giving the stolen jewels to the mother, supposing her to be the landlady. That Mr. Colman did no justice to this piece I honestly allow; that he told all his friends it would be damned, I positively aver; and from such ungenerous insinuations, without a dramatic merit, it rose to public notice, and it is now the ton to go and see it, though I never saw a person that either liked it or approved it, any more than the absurd plot of Home's tragedy of "Alonzo." Mr. Goldsmith, correct your arrogance, reduce your vanity, and endeavour to believe—as a man, you are of the plainest sort; and, as an author, but a mortal piece of mediocrity.

*Brise le miroir infidèle  
Qui vous cache la vérité.*

"TOM TICKLE."

It would be difficult to devise a letter more calculated to wound the peculiar sensibilities of Goldsmith. The attacks upon him as an author, though annoying enough, he could have tolerated; but then the allusion to his "grotesque" person, to his studious attempts to adorn it; and, above all, to his being an unsuccessful admirer of the lovely H—k (the Jessamy Bride), struck rudely upon the most sensitive part of his highly sensitive nature. The paragraph, it is said, was first pointed out to him by an officious friend, an Irishman, who told him he was bound in honour to resent it; but he needed no such prompting. He was in a high state of excitement and indignation, and, accompanied by his friend, who is said to have been a Captain Higgins of the marines, he repaired to Paternoster-row, to the shop of Evans, the publisher, whom he supposed to be the editor of the paper. Evans was summoned by his shopman from an adjoining room; Goldsmith announced his name. "I have called," added he, "in consequence of a scurrilous attack made upon me, and an unwarrantable liberty taken with the name of a young lady. As for myself, I care little; but her name must not be sported with."

Evans professed utter ignorance of the matter, and said he would speak to the editor. He stooped to examine a file of the paper, in search of the offensive article; whereupon Goldsmith's friend gave him a signal, that now was a favourable moment for the exercise of his cane. The hint was taken as quick as given, and the cane was vigorously applied to the back of the stooping publisher. The latter rallied in an instant, and, being a stout, high-blooded Welshman, returned the blows with interest. A lamp hanging overhead was broken, and sent down a shower of oil upon the combat

ants; but the battle raged with unceasing fury. The shopman ran off for a constable; but Dr. Kenrick, who happened to be in the adjacent room, sallied forth, interfered between the combatants, and put an end to the affray. He conducted Goldsmith to a coach, in exceedingly battered and tattered plight, and accompanied him home, soothing him with much mock commiseration, though he was generally suspected, and on good grounds, to be the author of the libel.

Evans immediately instituted a suit against Goldsmith for an assault, but was ultimately prevailed upon to compromise the matter, the poet contributing fifty pounds to the Welsh charity.

Newspapers made themselves, as may well be supposed, exceedingly merry with the combat. Some censured him severely for invading the sanctity of a man's own house; others accused him of having, in his former capacity of editor of a magazine, been guilty of the very offences that he now resented in others. This drew from him the following vindication:—

*"To the Public."*

"Lest it should be supposed that I have been willing to correct in others an abuse of which I have been guilty myself, I beg leave to declare, that in all my life I never wrote or dictated a single paragraph, letter, or essay in a newspaper, except a few moral essays under the character of a Chinese, about ten years ago in the "*Ledger*," and a letter, to which I signed my name, in the "*St. James's Chronicle*." If the liberty of the press, therefore, has been abused, I have had no hand in it.

"I have always considered the press as the protector of our freedom, as a watchful guardian, capable of uniting the weak against the encroachments of power. What concerns the public most properly admits of a public discussion. But, of late, the press has turned from defending public interest to making inroads upon private life—from combating the strong to overwhelming the feeble. No condition is now obscure for its abuse, and the protector has become the tyrant of the people. In this manner, the freedom of the press is beginning to sow the seeds of its own dissolution; the great must oppose it from principle, and the weak from fear; till at last every rank of mankind shall be found to give up its benefits, content with security from insults.

"How to put a stop to this licentiousness, by which all are indiscriminately abused, and by which vice consequently escapes in the general censure, I am unable to tell; all I could wish is, that, as the law gives us no protection against the injury, so it should give calumniators no shelter after having provoked correction. The insults which we receive before the public, by being more open, are the more distressing; by treating them with silent contempt, we do not pay a sufficient deference to the opinion of the world. By recurring to legal redress, we too often expose the weakness of the law, which only serves to increase our mortification by failing to relieve us. In short, every man should singly consider himself as the guardian of the liberty of the press, and, as far as his influence can extend, should endeavour to prevent its licentiousness becoming at last the grave of its freedom.

*"OLIVER GOLDSMITH."*

Boswell, who had just arrived in town, met with this article in a newspaper which he found at Dr. Johnson's. The doctor was from home at the time, and Bozzy and Mrs. Williams, in a critical conference over the letter, determined from the style that it must have been written by the lexicographer himself. The latter on his return soon undeceived them. "Sir," said he to Boswell, "Goldsmith would no more have asked me to have wrote such a thing as that for him, than he would have asked me to feed him with a spoon, or do anything else that denoted his imbecility. Sir, had he shown it to any one friend, he would not have been allowed to

publish it. He has, indeed, done it very well; but it is a foolish thing well done. I suppose he has been so much elated with the success of his new comedy, that he has thought everything that concerned him must be of importance to the public."

CHAP. XXXIX.

*Boswell in Holy-Week—Dinner at Oglethorpe's—Dinner at Paoli's—The policy of truth—Goldsmith affects independence of royalty—Paoli's compliment—Johnson's eulogium on the fiddle—Question about suicide—Boswell's subserviency.*

The return of Boswell to town to his task of noting down the conversations of Johnson, enables us to glean from his journal some scanty notices of Goldsmith. It was now Holy-Week—a time during which Johnson was particularly solemn in his manner and strict in his devotions. Boswell, who was the imitator of the great moralist in everything, assumed, of course, an extra devoutness on the present occasion. "He had an odd mock solemnity of tone and manner," said Miss Burney (afterwards Madame D'Arbly), "which he had acquired from constantly thinking of and imitating Dr. Johnson." It would seem that he undertook to deal out some second-hand homilies, *a la Johnson*, for the edification of Goldsmith during Holy-Week. The poet, whatever might be his religious feeling, had no disposition to be schooled by so shallow an apostle. "Sir," said he in reply, "as I take my shoes from the shoemaker, and my coat from the tailor, so I take my religion from the priest."

Boswell treasured up the reply in his memory or his memorandum-book. A few days afterwards, the 9th of April, he kept Good Friday with Dr. Johnson in orthodox style; breakfasted with him on tea and crossbuns; went to church with him morning and evening; fasted in the interval, and read with him in the Greek Testament; then, in the piety of his heart, complained of the sore rebuff he had met with in the course of his religious exhortations to the poet, and lamented that the latter should indulge in "this loose way of talking." "Sir," replied Johnson, "Goldsmith knows nothing—he has made up his mind about nothing."

This reply seems to have gratified the lurking jealousy of Boswell, and he has recorded it in his journal. Johnson, however, with respect to Goldsmith, and indeed with respect to everybody else, blew hot as well as cold, according to the humour he was in. Boswell, who was astonished and piqued at the continually increasing celebrity of the poet, observed some time after to Johnson, in a tone of surprise, that Goldsmith had acquired more fame than all the officers of the war who were not generals. "Why, sir," answered Johnson, his old feeling good-will working uppermost, "you will find ten thousand fit to do what they did, before you find one to do what Goldsmith has done. You must consider that a thing is valued according to its rarity. A pebble that paves the street is in itself more useful than the diamond upon a lady's finger."

On the 13th of April, we find Goldsmith and Johnson at the table of old General Oglethorpe, discussing the question of the degeneracy of the human race. Goldsmith asserts the fact, and attributes it to the influence of luxury. Johnson denies the fact; and observes, that even admitting it, luxury could not be the cause. It reached but a small proportion of the human race. Soldiers on sixpence a day could not indulge in luxuries; the poor and labouring classes, forming the great mass of mankind, were out of its sphere. Wherever it could reach them, it strengthened them and rendered them prolific. The conversation was not of particular force or point, as reported by Boswell: the dinner party was a very small one, in which there was no provocation to intellectual display.

After dinner they took tea with the ladies, where we find poor Goldsmith happy and at home, singing Tony Lumpkin's song of the "Three Jolly Pigeons," and another, called the "Humours of Ballamaguery," to a very pretty Irish tune. It was to have been introduced in "She Stoops to Conquer," but was left out, as the actress who played the heroine could not sing.

It was in these genial moments that the sunshine of Goldsmith's nature would break out, and he would say and do a thousand whimsical and agreeable things that made him the life of the strictly social circle. Johnson, with whom conversation was everything, used to judge Goldsmith too much by his own colloquial standard, and undervalue him for being less provided than himself with acquired facts, the ammunition of the tongue, and often the mere lumber of the memory; others, however, valued him for the native felicity of his thoughts, however carelessly expressed, and for certain good-fellow qualities, less calculated to dazzle than to endear. "It is amazing," said Johnson one day, after he himself had been talking like an oracle; "it is amazing how little Goldsmith knows; he seldom comes where he is not more ignorant than any one else." "Yet," replied Sir Joshua Reynolds, with affectionate promptness, "there is no man whose company is more liked."

Two or three days after the dinner at General Oglethorpe's, Goldsmith met Johnson again at the table of General Paoli, the hero of Corsica. Martinelli, of Florence, author of an Italian History of England, was among the guests; as was Boswell, to whom we are indebted for minutes of the conversation which took place. The question was debated whether Martinelli should continue his history down to that day. "To be sure he should," said Goldsmith. "No, sir," cried Johnson, "it would give great offence. He would have to tell of almost all the living great what they did not wish told." Goldsmith.—"It may, perhaps, be necessary for a native to be more cautious; but a foreigner, who comes among us without prejudice, may be considered as holding the place of a judge, and may speak his mind freely." Johnson.—"Sir, a foreigner, when he sends a work from the press, ought to be on his guard against catching the error and mistaken enthusiasm of the people among whom he happens to be." Goldsmith.—"Sir, he wants only to sell his history, and to tell truth; one an honest, the other a laudable motive." Johnson.—"Sir, they are both laudable motives. It is laudable in a man to wish to live by his labours; but he should write so as he may live by them, not so as he may be knocked on the head. I would advise him to be at Calais before he publishes his history of the present age. A foreigner who attaches himself to a political party in this country is in the worst state that can be imagined; he is looked upon as a mere intermeddler. A native may do it for interest." Boswell.—"Or principle." Goldsmith.—"There are people who tell a hundred political lies every day, and are not hurt by it. Surely, then, one may tell truth with perfect safety." Johnson.—"Why, sir, in the first place, he who tells a hundred lies has disarmed the force of his lies. But, besides, a man had rather have a hundred lies told of him than one truth which he does not wish to be told." Goldsmith.—"For my part, I'd tell the truth and shame the devil." Johnson.—"Yes, sir, but the devil will be angry. I wish to shame the devil as much as you do, but I should choose to be out of the reach of his claws." Goldsmith.—"His claws can do you no hurt where you have the shield of truth."

This last reply was one of Goldsmith's lucky hits, and closed the argument in his favour.

"We talked," writes Boswell, "of the king's coming to see Goldsmith's new play." "I wish he would," said Goldsmith, adding, however, with an affected indifference, "not that it would do me the least good." "Well, then," cried Johnson, laughing, "let us say it would do him good. No, sir, this affectation will not pass;—it is

mighty idle. In such a state as ours, who would not wish to please the chief magistrate?"

"I do wish to please him," rejoined Goldsmith. "I remember a line in Dryden:—

And every poet is the monarch's friend;  
it ought to be reversed." "Nay," said Johnson, "there are finer lines in Dryden on this subject:

For colleges on bounteous kings depend,  
And never rebel was to arts a friend.

General Paoli observed that "successful rebels might be." "Happy rebellions," interjected Martinelli. "We have no such phrase," cried Goldsmith. "But have you not the thing?" asked Paoli. "Yes," replied Goldsmith, "all our happy revolutions. They have hurt our constitutions, and will hurt it, till we mend it by another HAPPY REVOLUTION." This was a sturdy sally of Jacobitism that quite surprised Boswell, but must have been relished by Johnson.

General Paoli mentioned a passage in the play, which had been construed into a compliment to a lady of distinction, whose marriage with the Duke of Cumberland had excited the strong disapprobation of the king as a mésalliance. Boswell, to draw Goldsmith out, pretended to think the compliment unintentional. The poet smiled, and hesitated. The general came to his relief. "*Monsieur Goldsmith*," said he, "*est comme la mer, qui jette des perles et beaucoup d'autres belles choses, sans s'en apercevoir*." (Mr. Goldsmith is like the sea, which casts forth pearls and many other beautiful things without perceiving it.)

"*Très-bien dit, et très-élegamment*" (very well said, and very elegantly) exclaimed Goldsmith, delighted with so beautiful a compliment from such a quarter.

Johnson spoke disparagingly of the learning of a Mr. Harris, of Salisbury, and doubted his being a good Grecian. "He is what is much better," cried Goldsmith, with prompt good nature, "he is a worthy, humane man." "Nay, sir," rejoined the logical Johnson, "that is not to the purpose of our argument; that will prove that he can play upon a fiddle as well as Giardini, as that he is an eminent Grecian." Goldsmith found that he had got into a scrape, and seized upon Giardini to help him out of it. "The greatest musical performers," said he, dexterously turning the conversation, "have but small emoluments; Giardini, I am told, does not get above seven hundred a year." "That is indeed but little for a man to get," observed Johnson, "who does best that which so many endeavour to do. There is nothing, I think, in which the power of art is shown so much as in playing on the fiddle. In all other things we can do something at first. Any man will forge a bar of iron, if you give him a hammer—not so well as a smith, but tolerably. A man will saw a piece of wood, and make a box, though a clumsy one; but give him a fiddle and a fiddlestick, and he can do nothing."

This upon the whole, though reported by the one-sided Boswell, is a tolerable specimen of the conversations of Goldsmith and Johnson; the former heedless, often illogical, always on the kind-hearted side of the question, and prone to redeem himself by lucky hits; the latter closely argumentative, studiously sententious, often profound, and sometimes laboriously prosaic.

They had an argument a few days later at Mr. Thrale's table, on the subject of suicide. "Do you think, sir," said Boswell, "that all who commit suicide are mad?" "Sir," replied Johnson, "they are not often universally disordered in their intellects, but one passion presses so upon them that they yield to it, and commit suicide, as a passionate man will stab another. I have often thought," added he, "that after a man has taken the resolution to kill himself, it is not courage in him to do anything, however desperate, because he has nothing to fear." "I don't see that," observed Goldsmith. "Nay, but my dear sir," rejoined Johnson, "why should you not see what every one else does?" "It is," replied

Goldsmith, "for fear of something that he has resolved to kill himself; and will not that timid disposition restrain him?" "It does not signify," pursued Johnson, "that the fear of something made him resolve; it is upon the state of his mind, after the resolution is taken, that I argue. Suppose a man, either from fear, or pride, or conscience, or whatever motive, has resolved to kill himself; when once the resolution is taken he has nothing to fear. He may then go and take the King of Prussia by the nose at the head of his army. He cannot fear the rack who is determined to kill himself." Boswell reports no more of the discussion, though Goldsmith might have continued it with advantage; for the very timid disposition which, through fear of something, was impelling the man to commit suicide, might restrain him from an act involving the punishment of the rack, more terrible to him than death itself.

It is to be regretted in all these reports by Boswell we have scarcely anything but the remarks of Johnson; it is only by accident that he now and then gives us the observations of others, when they are necessary to explain or set off those of his hero. "When in *that presence*," says Miss Burney, "he was unobservant, if not contemptuous, of every one else. In truth, when he met with Dr. Johnson, he commonly forbore even answering anything that was said, or attending to anything that went forward, lest he should miss the smallest sound from that voice, to which he paid such exclusive, though merited homage. But the moment that voice burst forth, the attention which it excited on Mr. Boswell amounted almost to pain. His eyes goggled with eagerness; he leant his ear almost on the shoulder of the Doctor; and his mouth dropped open to catch every syllable that might be uttered; nay, he seemed not only to dread losing a word, but to be anxious not to miss a breathing; as if hoping from it latently, or mystically, some information."

On one occasion the doctor detected Boswell, or Bozzy as he called him, eavesdropping behind his chair, as he was conversing with Miss Burney at Mr. Thrale's table. "What are you doing there, sir?" cried he, turning round angrily, and clapping his hand upon his knee; "go to the table, sir."

Boswell obeyed, with an air of affright and submission which raised a smile on every face. Scarce had he taken his seat, however, at a distance, than, impatient to get again at the side of Johnson, he rose and was running off in quest of something to show him, when the doctor roared after him authoritatively, "What are you thinking of, sir? why do you get up before the cloth is removed? Come back to your place, sir!"—and the obsequious spaniel did as he was commanded.—"Running about in the middle of meals!" muttered the doctor, pursing his mouth at the same time to restrain his rising risibility.

Boswell got another rebuff from Johnson, which would have demolished any other man. He had been teasing him with many direct questions, such as "What did you do, sir?"—"What did you say, sir?" until the philologist became perfectly enraged. "I will not be put to the question!" roared he. "Don't you consider, sir, that these are not the manners of a gentleman? I will not be baited with *what* and *why*—What is this? What is that! Why is a cow's tail long? Why is a fox's tail bushy?" "Why, sir," replied pil-garlick, "you are so good that I venture to trouble you." "Sir," replied Johnson, "my being so good is no reason why you should be so ill." "You have but two topics, sir," exclaimed he on another occasion—"yourself and me, and I am sick of both."

Boswell's inveterate disposition to *toad* was a sore cause of mortification to his father, the old laird of Auchinleck (or Affleck). He had been annoyed by his extravagant devotion to Paoli, but then he was something of a military hero; but this tagging at the heels

of Dr. Johnson, whom he considered a kind of pedagogue, set his Scotch blood in a ferment. "There's nae hope for Jamie, mon," said he to a friend; "Jamie is gaen clean gyte. What do you think, mon? He's done wi' Paoli; he is off wi' the land-louping scoundrel of a Corsican; and whose tail do you think he has pinn'd himself to now, mon? A dominie, mon; an auld dominie: he kept a schule, and cau'd it an acaadamy."

We shall show in the next chapter that Jamie's devotion to the dominie did not go unrewarded.

## CHAP. XL

Changes in the Literary Club—Johnson's objection to Garrick—Election of Boswell.

The Literary Club (as we have termed the club in Gerard-street, though it took that name some time later) had now been in existence several years. Johnson was exceedingly chary at first of its exclusiveness and opposed to its being augmented in number. Not long after its institution Sir Joshua Reynolds was speaking of it to Garrick. "I like it much," said little David, briskly; "I think I shall be of you." When Sir Joshua mentioned this to Dr. Johnson, says Boswell, "he was much displeased with the actor's conceit. '*He'll be of us!*' growled he; 'How does he know we will permit him? The first duke in England has no right to hold such language.'"

When Sir John Hawkins spoke favourably of Garrick's pretensions, "Sir," replied Johnson, "he will disturb us by his buffoonery." In the same spirit, he declared to Mr. Thrale that if Garrick should apply for admission he would black-ball him. "Who, sir?" exclaimed Thrale, with surprise; "Mr. Garrick—your friend, your companion—black-ball him!" "Why, sir," replied Johnson, "I love my little David dearly—better than all or any of his flatterers, do; but surely one ought to sit in a society like ours,

Unelbow'd by a gamester, pimp, or player."

The exclusion from the club was a sore mortification to Garrick, though he bore it without complaining. He could not help continually to ask questions about it—what was going on there?—whether he was ever the subject of conversation? By degrees the rigour of the club relaxed; some of the members grew negligent. Beauclerc lost his right of membership by neglecting to attend. On his marriage, however, with Lady Diana Spencer, daughter of the Duke of Marlborough, and recently divorced from Viscount Bolingbroke, he had claimed and regained his seat in the club. The number of members had likewise been augmented. The proposition to increase it originated with Goldsmith. "It would give," he thought, "an agreeable variety to their meetings: for there can be nothing new amongst us," said he; "we have travelled over each other's mind." Johnson was piqued at the suggestion. "Sir," said he, "you have not travelled over my mind, I promise you." Sir Joshua, less confident in the exhaustless fecundity of his mind, felt and acknowledged the force of Goldsmith's suggestion. Several new members, therefore, had been added; the first, to his great joy, was David Garrick. Goldsmith, who was now on cordial terms with him, had zealously promoted his election, and Johnson had given it his warm approbation. Another new member was Beauclerc's friend, Lord Charlemont; and a still more important one was Mr. (afterwards Sir William) Jones, the famous Orientalist, at that time a young lawyer of the Temple and a distinguished scholar.

To the great astonishment of the club, Johnson now proposed his devoted follower, Boswell, as a member. He did it in a note addressed to Goldsmith, who pre-

## CHAP. XLI.

sided on the evening of the 23rd of April. The nomination was seconded by Beauclerc. According to the rules of the club, the ballot would take place at the next meeting (on the 30th); there was an intervening week, therefore, in which to discuss the pretensions of the candidate. We may easily imagine the discussions that took place. Boswell had made himself absurd in such a variety of ways, that the very idea of his admission was exceedingly irksome to some of the members. "The honour of being elected into the Turk's Head Club," said the Bishop of St. Asaph, "is not inferior to that of being representative of Westminster and Surrey;" what had Boswell done to merit such an honour? What chance had he of gaining it? The answer was simple: he had been a persevering worshiper, if not sycophant, of Johnson. The great lexicographer had a heart to be won by apparent affection; he stood forth authoritatively in support of his vassal. If asked to state the merits of the candidate, he summed them up in an indefinite but comprehensive word of his own coining: he was *dubable*. He, moreover, gave insignificant hints, that if Boswell were kept out he should oppose the admission of any other candidate. No further opposition was made; in fact, none of the members had been so fastidious and exclusive in regard to the club as Johnson himself; and if he were pleased, they were easily satisfied: besides, they knew that, with all his faults, Boswell was a cheerful companion, and possessed lively social qualities.

On Friday, when the ballot was to take place, Beauclerc gave a dinner at his house in the Adelphi, where Boswell met several of the members who were favourable to his election. After dinner Beauclerc adjourned to the club, leaving Boswell in company with Lady Di Beauclerc until the fate of his election should be known. He sat, he says, in a state of anxiety, which even the charming conversation of Lady Di could not entirely dissipate. It was not long before tidings were brought of his election, and he was conducted to the place of meeting, where, besides the company he had met at dinner, Burke, Dr. Nugent, Garrick, Goldsmith, and Mr. William Jones were waiting to receive him. The club, notwithstanding all its learned dignity in the eyes of the world, could at times "unbend and play the fool" as well as less important bodies. Some of its jocose conversations have at times leaked out, and a society in which Goldsmith could venture to sing his song of "An Old Woman Tossed in a Blanket" could not be so very staid in its gravity. We may suppose, therefore, the jokes that had been passing among the members while awaiting the arrival of Boswell. Beauclerc himself could not have repressed his disposition for a sarcastic pleasantry. At least we have a right to presume all this from the conduct of Dr. Johnson himself.

With all his gravity he possessed a deep fund of quiet humour, and felt a kind of whimsical responsibility to protect the club from the absurd propensities of the very questionable associate he had thus inflicted on them. Rising, therefore, as Boswell entered, he advanced with a very doctorial air, placed himself behind a chair, on which he leaned as on a desk or pulpit, and then delivered, *ex cathedra*, a mock solemn charge, pointing out the conduct expected from him as a good member of the club; what he was to do, and especially what he was to avoid; including in the latter, no doubt, all those petty, prying, questioning, gossiping, babbling habits which had so often grieved the spirit of the lexicographer. It is to be regretted that Boswell has never thought proper to note down the particulars of this charge, which, from the well known characters and positions of the parties, might have furnished a parallel to the noted charge of Launcelot Gobbo to his dog.

Dinner at Dilly's—Conversations on natural history—Intermeddling of Boswell—Dispute about toleration—Johnson's rebuff to Goldsmith—His apology—Man-worship—Doctors Major and Minor—A farewell visit

A few days after the serio-comic scene of the elevation of Boswell into the Literary Club, we find that indefatigable biographer giving particulars of a dinner at the Dillys, booksellers in the Poultry, at which he met Goldsmith and Johnson, with several other literary characters. His anecdotes of the conversation of course go to glorify Dr. Johnson; for, as he observes in his biography, "his conversation alone, or what led to it, or was interwoven with it, is the business of this work." Still, on the present, as on other occasions, he gives unintentional and perhaps unavoidable gleams of Goldsmith's good sense, which show that the latter only wanted a less prejudiced and more impartial reporter, to put down the charge of colloquial incapacity so unjustly fixed upon him. The conversation turned upon the natural history of birds—a beautiful subject, on which the poet, from his recent studies, his habits of observation, and his natural tastes, must have talked with instruction and feeling; yet, though we have much of what Johnson said, we have only a casual remark or two of Goldsmith. One was on the migration of swallows, which he pronounced partial; "the stronger ones," said he "migrate, the others do not."

Johnson denied the brute creation the faculty of reason. "Birds," said he, "build by instinct; they never improve; they build their first nest as well as any one they ever build." "Yet we see," observed Goldsmith, "if you take away a bird's nest with the eggs in it, she will make a slighter nest and lay again." "Sir," replied Johnson, "that is because at first she has full time, and makes her nest deliberately. In the case you mention, she is pressed to lay, and must, therefore, make her nest quickly, and consequently it will be slight." "The nidification of birds," rejoined Goldsmith, "is what is least known in natural history, though one of the most curious things in it." While conversation was going on in this placid, agreeable, and instructive manner, the eternal meddler and busy-body, Boswell, must intrude to put it in a brawl. The Dillys were dissenters; two of their guests were dissenting clergymen; another, Mr. Top-lady, was a clergyman of the established church. Johnson himself was a zealous, uncompromising churchman. None but a Marplot like Boswell would have thought, on such an occasion and in such company, to broach the subject of religious toleration; but, as has been well observed, "it was his perverse inclination to introduce subjects that he hoped would produce difference and debate." In the present instance he gained his point. An animated dispute immediately arose, in which according to Boswell's report, Johnson monopolised the greater part of the conversation, not always treating the dissenting clergymen with the greatest courtesy, and even once wounding the feelings of the mild and amiable Bennet Langton by his harshness.

Goldsmith mingled a little in the dispute, and with some advantage, but was cut short by flat contradiction when most in the right. He sat for a time silent but impatient under such overbearing dogmatism, though Boswell, with his usual misinterpretation, attributes his "restless agitation" to a wish to *get in and shine*. "Finding himself excluded," continues Boswell, "he had taken his hat to go away, but remained for a time with it in his hand, like a gamester, who, at the end of a long night, lingers for a little while to see if he can have a favourable opportunity to finish with success." Once he was beginning to speak, when he was overpowered by the loud voice of Johnson, who was at the opposite end of the table, and did not perceive his attempt; whereupon he threw down, as it were, his hat and his

argument, and, darting an angry glance at Johnson, exclaimed in a bitter tone, "*Take it.*"

Just then one of the disputants was beginning to speak, when Johnson, uttering some sound as if about to interrupt him, Goldsmith, according to Boswell, seized the opportunity to vent his own *envy and spleen*, under pretext of supporting another person. "Sir," said he to Johnson, "the gentleman has heard you patiently for an hour; pray allow us now to hear him." It was a reproof in the lexicographer's own style, and he may have felt that he merited it; but he was not accustomed to be reproved. "Sir," said he sternly, "I was not interrupting the gentleman; I was only giving him a signal of my attention. Sir, *you are impertinent.*" Goldsmith made no reply, but after some time went away, having another engagement.

That evening, as Boswell was on the way with Johnson and Langton to the club, he seized the occasion to make some disparaging remarks on Goldsmith, which he thought would just then be acceptable to the great lexicographer. "It was a pity," he said, "that Goldsmith would on every occasion endeavour to shine, by which he so often exposed himself." Langton contrasted him with Addison, who, content with the fame of his writings, acknowledged himself unfit for conversation; and, on being taxed by a lady with silence in company, replied, "Madam, I have but ninenece in ready money, but I can draw for a thousand pounds." To this Boswell rejoined, that Goldsmith had a great deal of gold in his cabinet, but was always taking out his purse, "Yes, sir," chuckled Johnson, "and that so often an empty purse."

By the time Johnson arrived at the club, however, his angry feelings had subsided, and his native generosity and sense of justice had got the uppermost. He found Goldsmith in company with Burke, Garrick, and other members, but sitting silent and apart, "brooding," as Boswell says, "over the reprimand he had received." Johnson's good heart yearned towards him; and knowing his placable nature, "I'll make Goldsmith forgive me," whispered he; then, with a loud voice, "Dr. Goldsmith," said he "something passed to-day where you and I dined—I ask your pardon." The ire of the poet was extinguished in an instant, and his grateful affection for the magnanimous though sometimes overbearing moralist rushed to his heart. "It must be much from you, sir," said he, "that I take ill!" "And so," adds Boswell, "the difference was over, and they were on as easy terms as ever, and Goldsmith rattled away as usual." We do not think these stories tell to the poet's disadvantage, even though related by Boswell.

Goldsmith, with all his modesty, could not be ignorant of his proper merit; and must have felt annoyed at times at being undervalued and elbowed aside by light-minded or dull men, in their blind and exclusive homage to the literary autocrat. It was a fine reproof he gave to Boswell on one occasion, for talking of Johnson as entitled to the honour of exclusive superiority: "Sir, you are for making a monarchy what should be a republic." On another occasion, when he was conversing in company with great vivacity, and apparently to the satisfaction of those around him, an honest Swiss who sat near, one George Michael Moser, keeper of the Royal Academy, perceiving Dr. Johnson rolling himself as if about to speak, exclaimed, "Stay, stay! Doctor Shonson is going to say something." "And are you sure, sir," replied Goldsmith, sharply, "that you can comprehend what he says?"

This clever rebuke, which gave the main zest to the anecdote, is omitted by Boswell, who probably did not perceive the point of it.

He relates another anecdote of this kind. On the authority of Johnson himself. The latter and Goldsmith were one evening in company with the Rev. George Graham, a master of Eton, who, notwithstanding the

sobriety of his cloth, had got intoxicated "to a pitch of looking at one mau and talking to another." "Doctor," cried he, in an ecstasy of devotion and good will, but goggling by mistake upon Goldsmith, "I should be glad to see you at Eton." "I shall be glad to wait upon you," replied Goldsmith. "No, no!" cried the other eagerly; "'tis not you I mean, Doctor *Minor*, 'tis Doctor *Major* there!" "You may easily conceive," said Johnson, in relating the anecdote, "what effect this had upon Goldsmith, who was irascible as a hornet." The only comment, however, which he is said to have made, partakes more of quaint and dry humour than bitterness; "that Graham," said he, "is enough to make one commit suicide." What more could be said to tolerate the nuisance of a consummate bore?

We have now given the last scenes between Goldsmith and Johnson which stand recorded by Boswell. The latter called on the poet a few days after the dinner at Dilly's to take leave of him prior to departing for Scotland; yet, even in this last interview, he contrives to get up a charge of "jealousy and envy." Goldsmith, he would fain persuade us, is very angry that Johnson is going to travel with him in Scotland; and endeavours to persuade him that he will be a dead weight "to lug along through the Highlands and Hebrides." Any one else, knowing the character and habits of Johnson, would have thought the same; and no one but Boswell would have supposed his office of bear-leader to the *ursa-major* a thing to be envied.\*

## CHAP. XLII.

Project of a "Dictionary of Arts and Sciences"—Disappointment—Negligent authorship—Application for a pension—Beattie's "Essay on Truth"—Public adulation—A high-minded rebuke.

The works which Goldsmith had still in hand being already paid for, and the money gone, some new scheme must be devised to provide for the past and the future—for impending debts, which threatened to crush him, and expenses which were continually increasing. He now projected a work of greater compass than any he had yet undertaken—a "Dictionary of Arts and Sciences" on a comprehensive scale, which was to occupy a number of volumes. For this he received promises of assistance from several powerful hands. Johnson was to contribute an article on ethics; Burke, an abstract of his Essay on the Sublime and the Beautiful, an essay on the Berkeleyan system of philosophy, and others on political science; Sir Joshua Reynolds, an essay on painting; and Garrick, while he undertook on his own part to furnish an essay on acting, engaged Dr. Burney to contribute an article on music. Here was a great array of talent positively engaged, while other writers of eminence were to be sought for the various departments of science, Goldsmith was to edit the whole.

\* One of Peter Pindar's (Dr. Wolcot) most amusing "*jeux d'esprit*" is his congratulatory epistle to Boswell on this tour, of which we subjoin a few lines:—

"O Boswell, Bozzy, Bruce, whate'er thy name,  
Thou mighty shark for anecdote and fame;  
Thou jackal, leading lion Johnson forth,  
To eat M'Pherson 'midst his native north;  
To frighten grave professors with his roar,  
And shake the Hebrides from shore to shore.

Bless'd be thy labours, most adventurous Bozzy,  
Bold rival of Sir John and Dame Piozzi;  
Heavens! with what laurels shall thy head be crown'd!  
A grove, a forest, shall thy ears surround!  
Yes! whilst the Rambler shall a comet blaze,  
And gild a world of darkness with his rays,  
Thee, too, that world with wonderment shall hail,  
A lively bouncing cracker at his tail!"

An undertaking of this kind, while it did not incessantly task and exhaust his inventive powers by original composition, would give agreeable and profitable exercise to his taste and judgment in selecting, compiling, and arranging, and be calculated to diffuse over the whole the acknowledged grace of his style.

He drew up a prospectus of the plan, which is said by Bishop Percy, who saw it, to have been written with uncommon ability, and to have had that perspicuity and elegance for which his writings are remarkable. This paper, unfortunately, is no longer in existence.

Goldsmith's expectations, always sanguine respecting any new plan, were raised to an extraordinary height by the present project; and well they might be, when we consider the powerful coadjutors already pledged. They were doomed, however, to complete disappointment. Davies, the bibliopole of Russell-street, lets us into the secret of this failure. "The booksellers," said he, "notwithstanding they had a very good opinion of his abilities, yet were startled at the bulk, importance, and expense of so great an undertaking, the fate of which was to depend on the industry of a man, with whose indolence of temper and method of procrastination they had long been acquainted."

Goldsmith certainly gave reason for some such distrust by the heedlessness with which he conducted his literary undertakings. Those unfinished, but paid for, would be suspended, to make way for some job that was to provide for present necessities. Those thus hastily taken up would be as hastily executed, and the whole, however pressing, would be shoved aside and left "at loose ends," on some sudden call to social enjoyment or recreation.

Cradoek tells us that on one occasion, when Goldsmith was hard at work on his Natural History, he sent to Dr. Percy and himself, entreating them to finish some pages of his work which lay upon his table, and for which the press was urgent, he being detained by other engagements at Windsor. They met by appointment at his chambers in the Temple, where they found everything in disorder, and costly books lying scattered about on the table and on the floor; many of the books on natural history, which he had recently consulted, lay open among uncorrected proof-sheets. The subject in hand, and from which he had suddenly broken off, related to birds. "Do you know anything about birds?" asked Dr. Percy, smiling. "Not an atom," replied Cradoek; "do you?" "Not I! I scarcely know a goose from a swan: however, let us try what we can do." They set to work and completed their friendly task. Goldsmith, however, when he came to revise it, made such alterations that they could neither of them recognise their own share. The engagement at Windsor, which had thus caused Goldsmith to break off suddenly from his multifarious engagements, was a party of pleasure with some literary ladies. Another anecdote was current, illustrative of the carelessness with which he executed works requiring accuracy and research. On the 22nd of June he had received payment in advance for a Grecian History in two volumes, though only one was finished. As he was pushing on doggedly at the second, Gibbon the historian called in. "You are the man of all others I wish to see," cried the poet, glad to be saved the trouble of reference to his books. "What was the name of that Indian king who gave Alexander the Great so much trouble?" "Montezuma," replied Gibbon, sportively. The heedless author was about committing the name to paper without reference, when Gibbon pretended to recollect himself, and gave the true name, Porus.

This story, very probably, was a sportive exaggeration; but it was a multiplicity of anecdotes like this and the preceding one, some true and some false, which had impaired the confidence of booksellers in Goldsmith as a man to be relied on for a task requiring wide and

accurate research, and close and long-continued application. The project of the Universal Dictionary, therefore, met with no encouragement, and fell through.

The failure of this scheme, on which he had built such spacious hopes, sank deep into Goldsmith's heart. He was still further grieved and mortified by the failure of an effort made by some of his friends to obtain for him a pension from government. There had been a talk of the disposition of the ministry to extend the bounty of the crown to distinguished literary men in pecuniary difficulty, without regard to their political creed: when the merits and claims of Goldsmith, however, were laid before them, they met no favour. The sin of sturdy independence lay at his door. He had refused to become a ministerial hack when offered a *carte blanche* by Parson Scott, the cabinet emissary. The wondering parson had left him in poverty and "his garret," and there the ministry were disposed to suffer him to remain.

In the meantime Dr. Beattie came out with his Essay on Truth, and all the orthodox world are thrown into a paroxysm of contagious ecstacy. He is cried up as the great champion of Christianity against the attacks of modern philosophers and infidels; he is fêted and flattered in every way. He receives at Oxford the honorary degree of doctor of civil law at the same time with Sir Joshua Reynolds. The king sends for him, praises his Essay, and gives him a pension of two hundred pounds.

Goldsmith feels more acutely the denial of a pension to himself, when one has thus been given unsolicited to a man he might without vanity consider so much his inferior. He was not one to conceal his feelings. "Here's such a stir," said he one day at Thrall's table, "about a fellow that has written one book, and I have written so many."

"Ah, Doctor!" exclaimed Johnson, in one of his caustic moods, "there go two and forty sixpences, you know, to one guinea." This is one of the cuts at poor Goldsmith in which Johnson went contrary to head and heart in his love for saying what is called a "good thing." No one knew better than himself the comparative superiority of the writings of Goldsmith; but the jingle of the sixpences and the guinea was not to be resisted.

"Everybody," exclaimed Mrs. Thrall, "loves Dr. Beattie but Goldsmith, who says he cannot bear the sight of so much applause as they all bestow upon him. Did he not tell us so himself, no one would believe he was so exceedingly ill-natured."

He told them so himself because he was too open and unreserved to disguise his feelings, and because he really considered the praise lavished on Beattie extravagant, as in fact it was. It was all, of course, set down to sheer envy and uncharitableness. To add to his annoyance, he found his friend Sir Joshua Reynolds joining in the universal adulation. He had painted a full length portrait of Beattie, decked in the doctor's robes in which he had figured at Oxford, with the "Essay on Truth" under his arm, and the angel of truth at his side, while Voltaire figured as one of the demons of infidelity, sophistry, and falsehood, driven into utter darkness.

Goldsmith had known Voltaire in early life; he had been his admirer and his biographer; he grieved to find him receiving such an insult from the classic pencil of his friend. "It is unworthy of you," said he to Sir Joshua, "to debase so high a genius as Voltaire before so mean a writer as Beattie. Beattie and his book will be forgotten in ten years, while Voltaire's fame will last for ever. Take care it does not perpetuate this picture to the shame of such a man as you." This noble and high-minded rebuke is the only instance on record of any reproachful words between the poet and the painter: and we are happy to find that it did not destroy the harmony of their intercourse.

## CHAP. XLIII

Toil without hope—The poet in the green-room—In the flower-garden—At Vauxhall—Dissipation without gaiety—Craddock in town—Friendly sympathy—A parting scene—An invitation to pleasure.

Thwarted in the plans and disappointed in the hopes which had recently cheered and animated him, Goldsmith found the labour at his half-finished tasks doubly irksome, from the consciousness that the completion of them could not relieve him from his pecuniary embarrassments. His impaired health, also, rendered him less capable than formerly of sedentary application, and continual perplexities disturbed the flow of thought necessary for original composition. He lost his usual gaiety and good humour, and became at times peevish and irritable. Too proud of spirit to seek sympathy or relief from his friends for the pecuniary difficulties he had brought upon himself by his errors and extravagance, and unwilling, perhaps, to make known their amount, he buried his cares and anxieties in his own bosom, and endeavoured in company to keep up his usual air of gaiety and unconcern. This gave his conduct an appearance of fitfulness and caprice, varying suddenly from moodiness to mirth, and from silent gravity to shallow laughter; causing surprise and ridicule in those who were not aware of the sickness of heart which lay beneath.

His poetical reputation, too, was sometimes a disadvantage to him; it drew upon him a notoriety which he was not always in the mood or the vein to act up to. "Good heavens! Mr. Foote" exclaimed an actress at the Haymarket Theatre, "what a humdrum kind of a man Dr. Goldsmith appears in our green-room, compared with the figure he makes in his poetry!" "The reason of that, madam," replied Foote, "is because the muses are better company than the players." Beauclerc's letters to his friend, Lord Charlemont, who was absent in Ireland, give us now and then an indication of the whereabouts of the poet during the present year. "I have been but once to the club since you left England," writes he; "we were entertained, as usual, with Goldsmith's absurdity." With Beauclerc everything was absurd that was not polished and pointed. In another letter he threatens, unless Lord Charlemont returns to England, to bring over the whole club, and let them loose upon him to drive him home by their peculiar habits of annoyance—Johnson shall spoil his books; Goldsmith shall *pull his flowers*; and last, and most intolerable of all, Boswell shall—talk to him. It would appear that the poet, who had a passion for flowers, was apt to pass much of his time in the garden when on a visit to a country seat, much to the detriment of the flower-beds and the despair of the gardener.

The summer wore heavily away with Goldsmith. He had not his usual solace of a country retreat; his health was impaired and his spirits depressed. Sir Joshua Reynolds, who perceived the state of his mind, kindly gave him much of his company. In the course of their interchange of thought, Goldsmith suggested to him the story of Ugolino as a subject for his pencil. The painting founded on it remains a memento of their friendship.

On the 4th of August we find them together at Vauxhall! at that time a place in high vogue, and which had once been to Goldsmith a scene of oriental splendour and delight. We have, in fact, in the "Citizen of the World," a picture of it as it had struck him in former years and in his happier moods. "Upon entering the gardens," says the Chinese philosopher, "I found every one sense occupied with more than expected pleasure—the lights everywhere glimmering through the scarcely-moving trees—the full-bodied concert bursting on the stillness of the night—the natural concert of the birds in the more retired part of the grove vying with

that which was formed by art—the company, gaily dressed, looking satisfaction, and the tables spread with various delicacies, all conspired to fill my imagination with the visionary happiness of the Arabian lawgiver, and lifted me into an ecstacy of admiration."

Everything now, however, is seen with different eyes; with him it is dissipation without pleasure; and he finds it impossible any longer, by mingling in the gay and giddy throng of apparently prosperous and happy beings, to escape from the carking care which is clinging to his heart.

His kind friend Craddock came up to town towards autumn, when all the fashionable world was in the country, to give his wife the benefit of a skilful dentist. He took lodgings in Norfolk-street, to be in Goldsmith's neighbourhood, and passed most of his mornings with him. "I found him," he says, "much altered, and at times very low. He wished me to look over and revise some of his works; but with a select friend or two, I was more pressing that he should publish by subscription his two celebrated poems of the 'Traveller' and the 'Deserted Village,' with notes." The idea of Craddock was, that the subscription would enable wealthy persons favourable to Goldsmith to contribute to his pecuniary relief without wounding his pride. "Goldsmith," said he, "readily gave up to me his private copies, and said 'Pray do what you please with them.' But whilst he sat near me, he rather submitted to than encouraged my zealous proceedings.

"I one morning called upon him, however, and found him infinitely better than I had expected; and, in a kind of exulting style, he exclaimed, 'Here are some of the best of my prose writings; *I have been hard at work since midnight*, and desire you to examine them.' 'These,' said I, 'are excellent indeed.' 'They are,' replied he, 'intended as an introduction to a body of arts and sciences.'

Poor Goldsmith was, in fact, gathering together the fragments of his shipwreck—the notes and essays, and memoranda collected for his Dictionary—and proposed to found on them a work in two volumes, to be entitled "A Survey of Experimental Philosophy."

The plan of the subscription came to nothing, and the projected "Survey" never was executed. The head might yet devise, but the heart was failing him; his talent at hoping, which gave him buoyancy to carry out his enterprises, was almost at an end.

Craddock's farewell scene with him is told in a simple but touching manner.

"The day before I was to set out for Leicestershire I insisted upon his dining with us. He replied, I will, but on one condition, that you will not ask me to eat anything.' 'Nay,' said I, 'this answer is absolutely unkind, for I had hoped, as we are supplied from the Crown and Anchor, that you would have named something you might have relished.' 'Well,' was the reply, 'if you will but explain it to Mrs. Craddock, I will certainly wait upon you.'

"The doctor found, as usual at my apartments, newspapers and pamphlets, and with a pen and ink he amused himself as well as he could. I had ordered from the tavern some fish, a roasted joint of lamb, and a tart; and the doctor either sat down or walked about, just as he pleased. After dinner he took some wine with biscuits; but I was obliged soon to leave him for awhile, as I had matters to settle prior to my next day's journey. On my return coffee was ready, and the doctor appeared more cheerful (for Mrs. Craddock was always rather a favourite with him), and in the evening he endeavoured to talk and remark as usual, but all was force. He stayed till midnight, and I insisted on seeing him safe home, and we most cordially shook hands at the Temple gate." Craddock little thought this was to be their final parting. He looked back to it with mournful recollections in after years, and lamented that

he had not remained longer in town, at every inconvenience, to solace the poor broken-spirited poet.

The latter continued in town all the autumn. At the opening of the Opera House, on the 20th of November. Mrs. Yates, an actress whom he held in great esteem, delivered a poetical exordium of his composition. Beauclerc, in a letter to Lord Charlemont, pronounced it very good, and predicted that it would soon be in all the papers. It does not appear, however, to have been ever published. In his fitful state of mind Goldsmith may have taken no care about it, and thus it has been lost to the world, although it was received with great applause by a crowded and brilliant audience.

A gleam of sunshine breaks through the gloom that was gathering over the poet. Towards the end of the year he receives another Christmas invitation to Barton. A country Christmas! with all the cordiality of the fireside circle, and the joyous revelry of the oaken hall—what a contrast to the loneliness of a bachelor's chambers in the Temple! It is not to be resisted. But how is poor Goldsmith to raise the ways and means? His purse is empty; his booksellers are already in advance to him. As a last resource, he applies to Garrick. Their mutual intimacy at Barton may have suggested him as an alternative. The old loan of forty pounds has never been paid; and Newbery's note, pledged as a security, has never been taken up. An additional loan of sixty pounds is now asked for, thus increasing the loan to one hundred; to insure the payment, he now offers, besides Newbery's note, the transfer of the comedy of the "Good-natured Man" to Drury Lane, with such alterations as Garrick may suggest. Garrick, in reply, evades the offer of the altered comedy, alludes significantly to a new one which Goldsmith had talked of writing for him, and offers to furnish the money required on his own acceptance.

The reply of Goldsmith bespeaks a heart brimful of gratitude, and overflowing with fond anticipations of Barton and the smiles of its fair residents. "My dear friend," writes he, "I thank you. I wish I could do something to serve you. I shall have a comedy for you in a season or two at the farthest, that I believe will be worth your acceptance, for I fancy I will make it a fine thing. You shall have the refusal. \* \* \* I will draw upon you one month after date for sixty pounds, and your acceptance will be ready money, *part of which I want to go down to Barton with.* May God preserve my honest little man, for he has my heart.—Ever,

"OLIVER GOLDSMITH."

And having thus scrambled together a little pocket money by hard contrivance, poor Goldsmith turns his back upon care and trouble, and Temple quarters, to forget for a time his desolate bachelorhood in the family circle and a Christmas fireside at Barton.

#### CHAP. XLIV.

A return to drudgery—Forced gaiety—Retreat to the country—The poem of "Retaliation"—Portrait of Garrick—of Goldsmith—of Reynolds—Illness of the Poet—His death—Grief of his friends—A last word respecting the Jessamy Bride.

The Barton festivities are over; Christmas, with all its home-felt revelry of the heart, has passed like a dream; the Jessamy Bride has beamed her last smile upon the poor poet, and the early part of 1774 finds him in his now dreary bachelor abode in the Temple, toiling fitfully and hopelessly at a multiplicity of tasks. His "Animated Nature," so long delayed, so often interrupted, is at length announced for publication, though it has yet to receive a few finishing touches. He is preparing a third "History of England," to be compressed and condensed in one volume for the use of schools. He is revising his "Inquiry into Polite Learning," for

which he receives the pittance of five guineas, much needed in his present scantiness of purse; he is arranging his "Survey of Experimental Philosophy," and he is translating the "Comic Romance of Scarron." Such is a part of the various labours of a drudging, depressing kind, by which his head is made wrong and his heart faint. "If there is a mental drudgery," says Sir Walter Scott, "which lowers the spirits and lacerates the nerves, like the toil of a slave, it is that which is exacted by literary composition when the head is employed. Add to the unhappy author's task sickness, sorrow, or the pressure of unfavourable circumstances, and the labour of the bondsman becomes light in comparison." Goldsmith again makes an effort to rally his spirits by going into gay society. "Our Club," writes Beauclerc to Charlemont, on the 12th of February, "has dwindled away to nothing. Sir Joshua and Goldsmith have got into such a round of pleasure that they have no time." This shows how little Beauclerc was the companion of the poet's mind, or could judge of him below the surface. Reynolds, the kind participator in joyless dissipation, could have told a different story of his companion's heart-sick gaiety.

In this forced mood Goldsmith gave entertainments in his chambers in the Temple, the last of which was a dinner to Johnson, Reynolds, and others of his intimates, who partook with sorrow and reluctance of his imprudent hospitality. The first course vexed them by its needless profusion. When a second, equally extravagant, was served up, Johnson and Reynolds declined to partake of it; and the rest of the company, understanding their motives, followed their example, and the dishes went from the table untasted. Goldsmith felt sensibly this silent and well-intended rebuke.

The gaieties of society, however, cannot medicine for any length of time a mind diseased. Wearied by the distractions and harassed by the expenses of a town life, which he had not the discretion to regulate, Goldsmith took the resolution, too tardily adopted, of retiring to the serene, quiet, and cheap and healthful pleasures of the country, and of passing only two months of the year in London. He accordingly made arrangements to sell his right in the Temple chambers, and in the month of March retired to his country quarters at Hyde, there to devote himself to toil. At this dispiriting juncture, when inspiration seemed to be at an end, and the poetic fire extinguished, a spark fell on his combustible imagination and set it in a blaze.

He belonged to a temporary association of men of talent, some of them members of the Literary Club, who dined together occasionally at the St. James's Coffee-house. At these dinners, as usual, he was one of the last to arrive. On one occasion, when he was more dilatory than usual, a whim seized the company to write epitaphs on him, as "The late Dr. Goldsmith," and several were thrown off in a playful vein, hitting off his peculiarities. The only one extant was written by Garrick, and has been preserved, very probably, from its pungency:—

Here lies poor Goldsmith, for shortness call'd Noll,  
Who wrote like an angel, but talk'd like poor poll.

Goldsmith did not relish the sarcasm, especially as coming from such a quarter. He was not very ready at repartee; but he took his time, and in the interval of his various tasks, concocted a series of epigrammatic sketches, under the title of "Retaliation," in which the characters of his distinguished intimates were admirably hit off, with a mixture of generous praise and good-humoured raillery. In fact, the poem—for its graphic truth, its nice discrimination, its terse good sense, and its shrewd knowledge of the world—must have electrified the club almost as much as the first appearance of "The Traveller," and let them still deeper into the character and talents of the man they had been accustomed to consider as their butt. Retaliation, in a

word, closed his accounts with the club, and balanced all his previous deficiencies.

The portrait of David Garrick is one of the most elaborate in the poem. When the poet came to touch it off he had some lurking piques to gratify, which the recent attack had revived. He may have forgotten David's cavalier treatment of him in the early days of his comparative obscurity; he may have forgiven his refusal of his plays; but Garrick had been capricious in his conduct in the times of their recent intercourse, sometimes treating him with gross familiarity, at other times affecting dignity and reserve, and assuming airs of superiority; frequently he had been facetious and witty in company at his expense, and lastly, he had been guilty of the couplet just quoted. Goldsmith, therefore, touched off the lights and shadows of his character with a free hand and at the same time gave a side-hit at his old rival Kelly, and his critical persecutor Kenrick, in making them sycophantic satellites of the actor. Goldsmith, however, was void of gall even in his revenge, and his very satire was more humorous than caustic:—

Here lies David Garrick, describe him who can,  
An abridgment of all that was pleasant in man;  
As an actor confess'd without rival to shine;  
As a wit, if not first, in the very first line;  
Yet, with talents like these, and an excellent heart,  
The man had his failings, a dupe to his art.  
Like an ill-judging beauty, his colours he spread,  
And beplaster'd with rouge his own natural red.  
On the stage he was natural, simple, affecting;  
'Twas only that when he was off he was acting.  
With no reason on earth to go out of his way,  
He turn'd and he varied full ten times a day:  
Though secure of our hearts, yet confoundedly sick  
If they were not his own by finessing and trick:  
He cast off his friends as a huntsman his pack,  
For he knew, when he pleased, he could whistle them back.  
Of praise a mere glutton, he swallow'd what came,  
And the puff of a dunce he mistook it for fame;  
Till his relish, grown callous almost to disease,  
Who pepper'd the highest was surest to please.  
But let us be candid, and speak out our mind—  
If dunces applauded, he paid them in kind.  
Ye Kenricks, ye Kellys, and Woodfalls so grave,  
What a commerce was yours, while you got and you gave!  
How did Grub-street re-echo the shouts that you raised,  
While he was be-Roscius'd and you were be-praised!  
But peace to his spirit, wherever it flies,  
To act as an angel and mix with the skies:  
Those poets who owe their best fame to his skill,  
Shall still be his flatterers, go where he will;  
Old Shakspeare receive him with praise and with love,  
And Beaumonts and Bens be his Kellys above.

This portion of "Retaliation" soon brought a retort from Garrick, which we insert as giving something of a likeness of Goldsmith, though in broad caricature:—

Here, Hermes, says Jove, who with nectar was mellow,  
Go fetch me some clay—I will make an odd fellow:  
Right and wrong shall be jumbled, much gold and some dross,  
Without cause be he pleased, without cause be he cross;  
Be sure, as I work, to throw in contradictions,  
A great love of truth, yet a mind turn'd to fictions;  
Now mix these ingredients, which, warm'd in the baking,  
Turn'd to learning and gaming, religion and raking,  
With the love of a wench, let his writings be chaste;  
Tip his tongue with strange matter, his lips with fine taste;  
That the rake and the poet o'er all may prevail,  
Set fire to the head and set fire to the tail;  
For the joy of each sex on the world I'll bestow it,  
This scholar, rake, Christian, dupe, gamester, and poet.  
Though a mixture so odd, he shall merit great fame,  
And among brother mortals be Goldsmith his name:  
When on earth this strange meteor no more shall appear,  
You, Hermes, shall fetch him to make us sport here.

The charge of raking so repeatedly advanced in the foregoing lines must be considered a sportive one, founded, perhaps, on an incident or two within Garrick's knowledge, but not borne out by the course of Goldsmith's life. He seems to have had a tender sentiment for the sex, but perfectly free from libertinism. Neither

was he an habitual gamester. The strictest scrutiny has detected no settled vice of the kind. He was fond of a game of cards, but an unskilful and careless player. Cards in those days were universally introduced into society. High play was, in fact, a fashionable amusement, as at one time was deep drinking: and a man might occasionally lose large sums, and be beguiled into deep potations, without incurring the character of a gamester or a drunkard. Poor Goldsmith, on his advent into high society, assumed fine notions with fine clothes; he was thrown occasionally among high players, men of fortune, who could sport their cool hundreds as carelessly as his early comrades at Ballymahon could their half-crowns. Being at all times magnificent in money matters, he may have played with them in their own way, without considering that what was sport to them, to him was ruin. Indeed, part of his financial embarrassments may have arisen from losses of this kind, incurred inadvertently, not in the indulgence of a habit. "I do not believe Goldsmith to have deserved the name of gamester," said one of his contemporaries; "he liked cards very well, as other people do, and lost and won occasionally: but as far as I saw or heard, and I had many opportunities of hearing, never any considerable sum. If he gam'd with any one, it was probably with Beauclerc, but I do not know that such was the case."

"Retaliation," as we have already observed, was never completed. Some characters, originally intended to be introduced, remained unattempted; others were but partially sketched—such was the one of Reynolds, the friend of his heart, and which he commenced with a felicity which makes us regret that it should remain unfinished:—

Here Reynolds is laid, and to tell you my mind,  
He has not left a wiser or better behind,  
His pencil was striking, resistless, and grand;  
His manners were gentle, complying, and bland;  
Still born to improve us in every part,  
His pencil our faces, his manners our heart.  
To coxcombs averse, yet most civilly steering,  
When they judg'd without skill he was still hard of hearing;  
When they talk'd of their Raphaels, Corregios, and stuff,  
He shifted his trumpet and only took snuff.  
By flattery unspoil'd—

The friendly portrait stood unfinished on the easel; the hand of the artist had failed! An access of a local complaint, under which he had suffered for some time past, added to a general prostration of health, brought Goldsmith back to town before he had well settled himself in the country. The local complaint subsided, but was followed by a low nervous fever. He was not aware of his critical situation, and intended to be at the club on the 25th of March, on which occasion Charles Fox, Sir Charles Bunbury (one of the Horneck connexion), and two other new members were to be present. In the afternoon, however, he felt so unwell as to take to his bed, and his symptoms soon acquired sufficient force to keep him there. His malady fluctuated for several days, and hopes were entertained of his recovery, but they proved fallacious. He had skilful medical aid and faithful nursing; but he would not follow the advice of his physicians, and persisted in the use of James's powders, which he had once found beneficial, but which were now injurious to him. His appetite was gone, his strength failed him, but his mind remained clear, and was perhaps too active for his frame. Anxieties and disappointments, which had previously sapped his constitution, doubtless aggravated his present complaint and rendered him sleepless. In reply to an inquiry of his physician, he acknowledged that his mind was ill at ease. This was his last reply; he was too weak to talk, and in general took no notice of what was said to him. He sank at last into a deep sleep, and it was hoped a favourable crisis had arrived. He awoke, however, in strong convulsions which continued without intermission until he expired, on the 4th

of April, 1774, at five o'clock in the morning, being in the forty-sixth year of his age.

His death was a shock to the literary world, and a deep affliction to a wide circle of intimates and friends; for, with all his foibles and peculiarities, he was fully as much beloved as he was admired. Burke, on hearing the news, burst into tears. Sir Joshua Reynolds threw by his pencil for the day, and grieved more than he had done in times of great family distress. "I was abroad at the time of his death," writes Dr. M'Donnell, the youth whom, when in distress, he had employed as an amanuensis, "and I wept bitterly when the intelligence first reached me. A blank came over my heart as if I had lost one of my nearest relatives, and was followed for some days by a feeling of despondency." Johnson felt the blow deeply and gloomily. In writing some time afterwards to Boswell, he observed, "Of poor Dr. Goldsmith there is little to be told more than the papers have made public. He died of a fever, made, I am afraid, more violent by uneasiness of mind. His debts began to be heavy, and all his resources were exhausted. Sir Joshua is of opinion that he owed no less than two thousand pounds. Was ever poet so trusted before?"

Among his debts were seventy-nine pounds due to his tailor, Mr. William Filby, from whom he had received a new suit but a few days before his death. "My father," said the younger Filby, "though a loser to that amount, attributed no blame to Goldsmith; he had been a good customer, and, had he lived, would have paid every farthing." Others of his tradespeople evinced the same confidence in his integrity, notwithstanding his heedlessness. Two sister milliners in Temple-lane, who had been accustomed to deal with him, were concerned when told, some time before his death, of his pecuniary embarrassments. "Oh, sir," said they to Mr. Cradock, "sooner persuade him to let us work for him gratis than apply to any other; we are sure he will pay us when he can."

On the stairs of his apartment there was the lamentation of the old and infirm and the sobbing of women, poor objects of his charity, to whom he had never turned a deaf ear, even when struggling himself with poverty.

But there was one mourner, whose enthusiasm for his memory, could it have been foreseen, might have soothed the bitterness of death. After the coffin had been screwed down, a lock of his hair was requested for a lady, a particular friend, who wished to preserve it as a remembrance. It was the beautiful Mary Horneck—the *Jessamy Bride*. The coffin was opened again, and a lock of hair cut off; which she treasured to her dying day. Poor Goldsmith! could he have foreseen that such a memorial of him was to be thus cherished!

One word more concerning this lady, to whom we have so often ventured to advert. She survived almost to the present day. Hazlitt met her at Northcote's painting-room, about twenty years since, as Mrs. Gwyn, the widow of a General Gwyn of the army. She was at that time upwards of seventy years of age. Still, he said, she was beautiful, beautiful even in years. After she was gone, Hazlitt remarked how handsome she still was. "I do not know," said Northcote, "why she is so kind as to come and see me, except that I am the last link in the chain that connects her with all those she most esteemed when young—Johnson, Reynolds, Goldsmith—and remind her of the most delightful period of her life." "Not only so," observed Hazlitt, "but you remember what she was at twenty; and you thus bring back to her the triumphs of her youth—that pride of beauty, which must be the more fondly cherished as it has no external vouchers, and lives chiefly in the bosom of its once lovely possessor. In her, however, the Graces had triumphed over time; she was one of Ninon de l'Enclos's people, of the last of the immortals. I

could almost fancy the shade of Goldsmith in the room, looking round with complacency."

The *Jessamy Bride* survived her sister upwards of forty years, and died in 1840, within a few days of completing her eighty-eighth year. "She had gone through all the stages of life," says Northcote, "and had lent a grace to each." However gaily she may have sported with the half-concealed admiration of the poor awkward poet in the heyday of her youth and beauty, and however much it may have been made a subject of teasing by her youthful companions, she evidently prided herself in after years upon having been an object of his affectionate regard; it certainly rendered her interesting throughout life in the eyes of his admirers, and has hung a poetical wreath above her grave.

#### CHAP. XLV.

The funeral—The monument—The epitaph—Concluding remarks.

In the warm feeling of the moment, while the remains of the poet were scarce cold, it was determined by his friends to honour them by a public funeral and a tomb in Westminster Abbey. His very pall-bearers were designated:—Lord Shelburne, Lord Lowth, Sir Joshua Reynolds, the Hon. Mr. Beauchamp, Mr. Burke, and David Garrick. This feeling cooled down, however, when it was discovered that he died in debt, and had not left wherewithal to pay for such expensive obsequies. Five days after his death, therefore, at five o'clock on Saturday evening, the 9th of April, he was privately interred in the burying-ground of the Temple Church; a few persons attending as mourners, among whom we do not find specified any of his peculiar and distinguished friends. The chief mourner was Sir Joshua Reynolds's nephew, Palmer, afterwards Dean of Cashel. One person, however, from whom it was but little to be expected, attended the funeral and evinced real sorrow on the occasion. This was Hugh Kelly, once the dramatic rival of the deceased, and often, it is said, his anonymous assailant in the newspapers. If he had really been guilty of this basest of literary offences, he was punished by the stings of remorse, for we are told that he shed bitter tears over the grave of the man he had injured. His tardy atonement only provoked the lash of some unknown satirist, as the following lines will show:—

Hence Kelly, who years, without honour or shame,  
Had been sticking his bodkin in Oliver's fame,  
Who thought, like the Tartar, by this to inherit  
His genius, his learning, simplicity, spirit;  
Now acts every feature to weep o'er his fate,  
And acts as a mourner to blubber in state.

One base wretch deserves to be mentioned, the reptile Kenrick, who, after having repeatedly slandered Goldsmith while living, had the audacity to insult his memory when dead. The following distich is sufficient to show his malignancy, and to hold him up to execration:—

By his own art, who justly died,  
A blundering, artless, suicide;  
Share, earthworms, share, since now he's dead,  
His megrim, maggot-bitten head.

This scurrilous epitaph produced a burst of public indignation, that awed for a time even the infamous Kenrick into silence. On the other hand, the press teemed with tributes in verse and prose to the memory of the deceased; all evincing the mingled feeling of admiration for the author and affection for the man.

Not long after his death the Literary Club set on foot a subscription, and raised a fund to erect a monument to his memory in Westminster Abbey. It was executed by Nollikens, and consisted simply of a bust of the poet in profile, in high relief, in a medallion, and was placed in the area of a pointed arch, over the south door in

Poet's Corner, between the monuments of Gay and the Duke of Argyll. Johnson furnished a Latin epitaph, which was read at the table of Sir Joshua Reynolds, where several members of the club and other friends of the deceased were present. Though considered by them a masterly composition, they thought the literary character of the poet not defined with sufficient exactness, and they preferred that the epitaph should be in English rather than Latin, as "the memory of so eminent an English writer ought to be perpetuated in the language to which his works were likely to be so lasting an ornament."

These objections were reduced to writing, to be respectfully submitted to Johnson; but such was the awe entertained of his frown, that every one shrank from putting his name first to the instrument; whereupon their names were written about it in a circle, making what mutinous sailors call a "Round Robin." Johnson received it half graciously, half grimly. "He was willing," he said, "to modify the sense of the epitaph in any manner the gentlemen pleased; but he never would consent to disgrace the walls of Westminster Abbey with an English inscription." Seeing the names of Dr. Warton and Edmund Burke among the signers, "he wondered," he said, "that Joe Warton, a scholar by profession, should be such a fool; and should have thought that Mund Burke would have had more sense." The following is the epitaph, as it stands inscribed on a white marble tablet beneath the bust:—

OLIVARIUS GOLDSMITH,  
Poetæ, Physici, Historici,  
Qui nullum fere scribendi genus  
Non tetigit,  
Nullum quod tetigit non ornavit;  
Sive risus essent movendi,  
Sive lacrymæ,  
Affectuum potens at lenis dominator:  
Ingenio sublimis, vividus, versatilis,  
Oratione grandis, nitidus, venustus:  
Hoc monumento memoriam coluit  
Sodalium amor,  
Amicorum fides,  
Lectorum veneratio  
Natus in Hibernia Fornie Longfordiensis,  
In loco cui nomen Pallas,  
Nov. XXIX. MDCCXXI.  
Eblanæ literis institutus;  
Obiit Londini,  
April IV. MDCCCLXXIV.\*

We shall not pretend to follow these anecdotes of the life of Goldsmith with any critical dissertation on his writings; their merits have long since been fully discussed, and their station in the scale of literary merit permanently established. They have outlasted generations of works of higher power and wider scope, and will continue to outlast succeeding generations, for they have

\* The following translation is from Croker's edition of Boswell's Johnson:—

OF OLIVER GOLDSMITH—  
A Poet, Naturalist, and Historian,  
Who left scarcely any style of writing  
untouched,  
And touched nothing that he did not adorn;  
Of all the passions,  
Whether smiles were to be moved  
or tears,  
A powerful yet gentle master;  
In genius, sublime, vivid, versatile—  
In style, elevated, clear, elegant;  
The love of companions,  
The fidelity of friends,  
And the veneration of readers,  
Have by this monument honoured the memory.  
He was born in Ireland,  
At a place called Pallas,  
[In the parish] of Forney, [and county] of Longford,  
On the 29th Nov., 1731;  
Educated at [the University of] Dublin;  
And died in London,  
4th April, 1774.

that magic charm of style by which works are embalmed to perpetuity. Neither shall we attempt a regular analysis of the character of the poet, but will indulge in a few desultory remarks in addition to those scattered throughout the preceding chapters.

Never was the trite, because sage apophthegm, that "the child is father to the man," more fully verified than in the case of Goldsmith. He is shy, awkward, and blundering in childhood, yet full of sensibility; he is a butt for the jeers and jokes of his companions, but apt to surprise and confound them by sudden and witty repartees; he is dull and stupid at his tasks, yet an eager and intelligent devourer of the travelling tales and campaigning stories of his half-military pedagogue; he may be a dunce, but he is already a rhymist; and his early scintillations of poetry awaken the expectations of his friends. He seems from infancy to have been compounded of two natures—one bright, the other blundering; or to have had fairy gifts laid in his cradle by the "good people" who haunted his birth-place, the old goblin mansions on the banks of the Inny.

He carries with him the wayward elfin spirit, if we may so term it, throughout his career. His fairy gifts are of no avail at school, academy, or college: they unfit him for close study and practical science, and render him heedless of everything that does not address itself to his poetical imagination and genial and festive feelings; they dispose him to break away from restraint, to stroll about hedges, lanes, and haunted streams, to revel with jovial companions, or to rove the country like a gipsy in quest of odd adventures.

As if confiding in these delusive gifts, he takes no heed of the present nor care for the future, lays no regular and solid foundation of knowledge, follows out no plan, adopts and disregards those recommended by his friends, at one time prepares for the ministry, next turns to the law, and then fixes upon medicine. He repairs to Edinburgh, the great emporium of medical science, but the fairy gifts accompany him; he idles and frolics away his time there, imbibing only such knowledge as is agreeable to him; makes an excursion to the poetical regions of the Highlands; and having walked the hospitals for the customary time, sets off to ramble over the continent, in quest of novelty rather than knowledge. His whole tour is a poetical one. He fancies he is playing the philosopher while he is really playing the poet; and though professedly he attends lectures and visits foreign universities, so deficient is he on his return in the studies for which he set out, that he fails in an examination as a surgeon's mate; and while figuring as a doctor of medicine, is outwitted on a point of practice by his apothecary. Baffled in every regular pursuit, after trying in vain some of the humbler callings of common-place life, he is driven almost by chance to the exercise of his pen, and here the fairy gifts come to his assistance. For a long time, however, he seems unaware of the magic properties of that pen: he uses it only as a makeshift until he can find a legitimate means of support. He is not a learned man, and can write but meagrely and at second-hand on learned subjects; but he has a quick convertible talent, that seizes lightly on the points of knowledge necessary to the illustration of a theme: his writings for a time are desultory, the fruits of what he has seen and felt, or what he has recently and hastily read; but his gifted pen transmutes everything into gold, and his own genial nature reflects its sunshine through his pages.

Still unaware of his powers, he throws off his writings anonymously, to go with the writings of less favoured men: and it is a long time, and after a bitter struggle with poverty and humiliation, before he acquires confidence in his literary talent as a means of support, and begins to dream of reputation.

From this time his pen is a wand of power in his hand, and he has only to use it discreetly, to make it

competent to all his wants. But discretion is not a part of Goldsmith's nature; and it seems the property of these fairy gifts to be accompanied by moods and temperaments to render their effect precarious. The heedlessness of his early days, his disposition for social enjoyment, his habits of throwing the present on the neck of the future, still continue. His expenses forerun his means; he incurs debts on the faith of what his magic pen is to produce, and then, under the pressure of his debts, sacrifices its productions for prices far below their value. It is a redeeming circumstance in his prodigality, that it is lavished oftener upon others than upon himself: he gives without thought or stint, and is the continual dupe of his benevolence and his trustfulness in human nature. We may say of him as he says of one of his heroes—"He could not stifle the natural impulse which he had to do good, but frequently borrowed money to relieve the distressed; and when he knew not conveniently where to borrow, he has been observed to shed tears as he passed through the wretched suppliants who attended his gate." \* \*

"His simplicity in trusting persons whom he had no previous reasons to place confidence in, seems to be one of those lights of his character which, while they impeach his understanding, do honour to his benevolence. The low and the timid are ever suspicious; but a heart impressed with honourable sentiments expects from others sympathetic sincerity."

His heedlessness in pecuniary matters, which had rendered his life a struggle with poverty, even in the days of his obscurity, rendered the struggle still more intense when his fairy gifts had elevated him into the society of the wealthy and luxurious, and imposed on his simple and generous spirit fancied obligations to a more ample and bounteous display.

"How comes it," says a recent and ingenious critic, "that in all the miry paths of life which he had trod, no speck ever sullied the robe of his modest and graceful muse? How, amidst all that love of inferior company, which never to the last forsook him, did he keep his genius so free from every touch of vulgarity?"

We answer that it was owing to the innate purity and goodness of his nature: there was nothing in it that assimilated to vice and vulgarity. Though his circumstances often compelled him to associate with the poor, they never could betray him into companionship with the depraved. His relish for humour and for the study of character, as we have before observed, brought him often into convivial company of a vulgar kind; but he discriminated between their vulgarity and their amusing qualities, or rather wrought from the whole those familiar features of life which form the staple of his most popular writings.

Much, too, of this intact purity of heart may be ascribed to the lessons of his infancy under the paternal roof; to the gentle, benevolent, elevated, unworldly maxims of his father, who, "passing rich with forty pounds a year," infused a spirit into his child which riches could not deprave nor poverty degrade. Much of his boyhood, too, had been passed in the household of his uncle, the amiable and generous Contarine; where he talked of literature with the good pastor, and practised music with his daughter, and delighted them both by his juvenile attempts at poetry. These early associations breathed a grace and refinement into his mind, and tuned it up after the rough sports on the green, or the frolics at the tavern. These led him to turn from the roaring glee of the club to listen to the harp of his cousin Jane; and from the rustic triumph of "throwing sledge" to a stroll with his flute along the pastoral banks of the Inny.

The gentle spirit of his father walked with him through life, a pure and virtuous monitor; and in all the vicissitudes of his career, we find him ever more chastened in mind by the sweet and holy recollections of the home of his infancy.

It has been questioned whether he really had any religious feeling. Those who raise the question have never considered well his writings; his "Vicar of Wakefield," and his pictures of "the Village Pastor," present religion under its most endearing forms, and with a feeling that could only flow from the deep convictions of the heart. When his fair travelling companions at Paris urged him to read the Church Service on a Sunday, he replied that "he was not worthy to do it." He had seen in early life the sacred offices performed by his father and his brother, with a solemnity which had sanctified them in his memory; how could he presume to undertake such functions? His religion has been called into question by Johnson and by Boswell: he certainly had not the gloomy hypochondriacal piety of the one, nor the babbling mouth piety of the other, but the spirit of Christian charity breathed forth in his writings and illustrated in his conduct give us reason to believe he had the indwelling religion of the soul.

We have made sufficient comments in the preceding chapters on his conduct in elevated circles of literature and fashion. The fairy gifts which took him there were not accompanied by the gifts and graces necessary to sustain him in that artificial sphere. He can neither play the learned sage with Johnson, nor the fine gentleman with Beauclerc, though he has a mind replete with wisdom and shrewdness, and a spirit free from vulgarity. The blunders of a fertile but hurried intellect, and the awkward display of the student assuming the man of fashion, fix on him a character for absurdity and vanity which, like the charge of lunacy, it is hard to disprove, however weak the grounds of the charge and strong the facts in opposition to it.

In truth, he is never truly in his place in these learned and fashionable circles, which talk and live for display. It is not the kind of society he craves. His heart yearns for domestic life; it craves familiar, confiding intercourse, family fireside, the guileless and happy company of children; these bring out the heartiest and sweetest sympathies of his nature.

"Had it been his fate," says the critic we have already quoted, "to meet a woman who could have loved him, despite his faults, and respected him despite his foibles, we cannot but think that his life and his genius would have been much more harmonious; his desultory affections would have been concentrated, his craving self-love appeased, his pursuits more settled, his character more solid. A nature like Goldsmith's, so affectionate, so confiding—so susceptible to simple, innocent enjoyments—so dependent on others for the sunshine of existence, does not flower if deprived of the atmosphere of home."

The cravings of his heart in this respect are evident, we think, throughout his career; and if we have dwelt with more significance than others upon his intercourse with the beautiful Horneck family, it is because we fancied we could detect, amid his playful attentions to one of its members, a lurking sentiment of tenderness, kept down by conscious poverty and a humiliating idea of personal defects. A hopeless feeling of this kind—the last a man would communicate to his friends—might account for much of that fitfulness of conduct and that gathering melancholy remarked, but not comprehended, by his associates during the last year or two of his life; and may have been one of the last troubles of the mind which aggravated his last illness, and only terminated with his death.

We shall conclude these desultory remarks with a few which have been used by us on a former occasion. From the general tone of Goldsmith's biography, it is evident that his faults at the worst were but negative, while his merits were great and decided. He was no one's enemy but his own; his errors, in the main, inflicted evil on none but himself, and were so blended with humorous and even affecting circumstances, as to disarm anger and conciliate kindness. Where eminent talent is united to

spotless virtue, we are awed and dazzled into admiration, but our admiration is apt to be cold and reverential; while there is something in the harmless infirmities of a good and great, but erring individual, that pleads touchingly to our nature; and we turn more kindly towards the object of our idolatry, when we find that, like ourselves, he is mortal and is frail. The epithet so often heard, and in such kindly tones, of "poor Goldsmith," speaks volumes. Few, who consider the real compound of admirable and whimsical qualities which form his character would wish to prune away its eccentricities,

trim its grotesque luxuriance, and clip it down to the decent formalities of rigid virtue. "Let not his frailties be remembered," said Johnson; "he was a very great man." But, for our part, we rather say "Let them be remembered," since their tendency is to endear: and we question whether he himself would not feel gratified in hearing his reader, after dwelling with admiration on the proofs of his greatness, close the volume with the kind-hearted phrase, so fondly and familiarly ejaculated, of—"Poor Goldsmith."

### CHAP. I.

#### A SKETCH OF THE UNIVERSE.

THE world may be considered as one vast mansion, where man has been admitted to enjoy, to admire, and to be grateful. The first desires of savage nature are merely to gratify the importunities of sensual appetite, and to neglect the contemplation of things, barely satisfied with their enjoyment; the beauties of Nature, and all the wonders of Creation, have but little charms for a being taking up in obviating the wants of the day, and anxious for precarious subsistence.

Our philosophers, therefore, who have testified such surprise at the want of curiosity in the ignorant, seem not to consider that they are usually employed in making provisions of a more important nature; in providing rather for the necessities than the amusements of life. It is not till our more pressing wants are sufficiently supplied, that we can attend to the calls of curiosity; so that in every age scientific refinement has been the latest effort of human industry.

But human curiosity, though at first slowly excited, being at last possessed of leisure for indulging its propensity, becomes one of the greatest amusements of life, and gives higher satisfactions than what even the senses can afford. A man of this disposition turns all nature into a magnificent theatre, replete with objects of wonder and surprise, and fitted up chiefly for his happiness and entertainment; he industriously examines all things, from the minutest insect to the most finished animal; and, when his limited organs can no longer make the disquisition, he sends out his imagination upon new inquiries.

Nothing, therefore, can be more august and striking than the idea which his reason, aided by his imagination, furnishes of the universe around him. Astronomers tell us, that this earth which we inhabit forms but a very minute part in that great assemblage of bodies of which the world is composed. It is a million of times less than the sun, by which it is enlightened. The planets also, which, like it, are subordinate to the sun's influence, exceed the earth one thousand times in magnitude. These, which were at first supposed to wander in the heavens without any fixed path, and that took their name from their apparent deviations, have long been found to perform their circuits with great exactness and strict regularity. They have been discovered as forming with our earth a system of bodies circulating round the sun, all obedient to one law, and impelled by one common influence.

Modern philosophy has taught us to believe, that, when the great Author of Nature began the work of creation, he chose to operate by second causes; and that, suspending the constant exertion of his power, he endued matter with a quality by which the universal economy of nature might be continued without his immediate assistance. This quality is called attraction; a sort of approximating influence, which all bodies, whether terrestrial or celestial, are found to possess; and which in all increases as the quantity of matter in each increases. The sun, by far the greatest body in our system, is, of consequence, possessed of much the greatest share of this attracting power; and all the planets, of which our earth is one, are, of course, entirely subject to its superior influence. Were this power, therefore, left uncontrolled by any other, the sun must quickly have attracted all the bodies of our celestial system to itself; but it is equally counteracted by another power of equal efficacy; namely, a progressive force which each planet received when it was impelled forward, by the divine Architect, upon its first formation. The heavenly bodies of our system being thus acted upon by two opposing powers; namely, by that of attraction, which draws them towards the sun; and that of impulsion, which drives them straight forward into the great void of space; they pursue a track between these contrary directions; and each, like a stone whirled about in a sling, obeying two opposite forces, circulates round its great centre of heat and motion.

In this manner, therefore, is the harmony of our planetary system preserved. The sun, in the midst, gives heat, and light, and circular motion to the planets which surround it; Mercury, Venus, the Earth, Mars, Jupiter, and Saturn, perform their constant circuits at different distances, each taking up a time to complete its revolutions proportioned to the greatness of the circle which it is to describe. The lesser planets also, which are attendants upon some of the greater, are subject to the same laws; they circulate with the same exactness; and are, in the same manner, influenced by their respective centres of motion.

Besides those bodies which make a part of our peculiar system, and which may be said to reside within its great circumference, there are others, that frequently come among us from the most distant tracts of space, and that seem like dangerous intruders upon the beautiful simplicity of nature. These are comets, whose appearance was once so terrible to mankind, and the theory of which is so little understood at present: all we know is, that their number is greater than that of the planets; and that, like these, they roll in orbits, in some measure

obedient to solar influence. Astronomers have endeavoured to calculate the returning periods of many of them; but experience has not, as yet, confirmed the veracity of their investigations. Indeed, who can tell when those wanderers have made their excursions into other worlds and distant systems, what obstacles may be found to oppose their progress, to accelerate their motions, or retard their return?

But what we have hitherto attempted to sketch, is but a small part of the great fabric in which the Deity has thought proper to manifest his wisdom and omnipotence. There are multitudes of other bodies dispersed over the face of the heavens that lie too remote for examination: these have no motion, such as the planets are found to possess, and are therefore called fixed stars; and from their extreme brilliancy, and their immense distance, philosophers have been induced to suppose them to be suns resembling that which enlivens our system. As the imagination also, once excited, is seldom content to stop, it has furnished each with an attendant system of planets belonging to itself, and has even induced some to deplore the fate of those systems, whose imagined suns, which sometimes happens, have become no longer visible.

But conjectures of this kind, which no reasoning can ascertain, nor experiment reach, are rather amusing than useful. Though we see the greatness and wisdom of the Deity in all the seeming worlds that surround us, it is our chief concern to trace him in that which we inhabit. The examination of the earth, the wonders of its contrivance, the history of its advantages, or of the seeming defects in its formation, are the proper business of the natural historian. A description of this earth, its animals, vegetables, and minerals, is the most delightful entertainment the mind can be furnished with, as it is most interesting and useful. I would beg leave, therefore, to conclude these common-place speculations, with an observation which, I hope, is not entirely so. An use, hitherto not much insisted upon, that may result from the contemplation of celestial magnificence, is that it will teach us to make an allowance for the apparent irregularities we find below. Whenever we can examine the works of the Deity at a proper point of distance, so as to take in the whole of His design, we see nothing but uniformity, beauty, and precision. The heavens present us with a plan, which, though inexpressibly magnificent, is yet regular beyond the power of invention. Whenever, therefore, we find any apparent defects in the earth, which we are about to consider, instead of attempting to reason ourselves into an opinion that they are beautiful, it will be wiser to say, that we do not behold them at the proper point of distance, and that our eye is laid too close to the objects to take in the regularity of their connexion. In short, we may conclude that God, who is regular in his great productions, acts with equal uniformity in the little.

## CHAP. II.

### A SHORT SURVEY OF THE GLOBE, FROM THE LIGHT OF ASTRONOMY AND GEOGRAPHY.

All the sciences are in some measure linked with each other, and before the one is ended the other begins. In a natural history, therefore, of the earth, we must begin with a short account of its situation and form, as given us by astronomers and geographers; it will be sufficient, however, upon this occasion, just to hint to the imagination what they, by the most abstract reasonings, have forced upon the understanding. The earth which we inhabit is, as has been said before, one of those bodies which circulate in our solar system; it is placed at a happy middle distance from the centre, and even seems in this respect privileged beyond all other planets that

depend upon our great luminary for their support. Less distant from the sun than Saturn, Jupiter, and Mars, and yet less parched up than Venus and Mercury, which are situated too near the violence of its power, the earth seems in a peculiar manner to share the bounty of the Creator: it is not, therefore, without reason that mankind consider themselves as the peculiar objects of His providence and regard.

Besides that motion which the earth has round the sun, the circuit of which is performed in a year, it has another upon its own axle, which it performs in twenty-four hours. Thus, like a chariot wheel, it has a compound motion; for while it goes forward on its journey, it is all the while turning upon itself. From the first of these two arises the grateful vicissitude of the seasons; from the second, that of day and night.

It may be also readily conceived, that a body thus wheeling in circles will most probably be itself a sphere. The earth, beyond all possibility of doubt, is found to be so. Whenever its shadow happens to fall upon the moon, in an eclipse, it appears to be always circular, in whatever position it is projected; and it is easy to prove that a body which in every position makes a circular shadow must itself be round. The rotundity of the earth may be also proved from the meeting of two ships at sea; the topmasts of each are the first parts that are discovered by both, the under parts being hidden by the convexity of the globe which rises between them. The ships in this instance may be likened to two men who approach each other on the opposite sides of a hill; their heads will first be seen, and gradually as they come nearer they will come entirely into view.

However, though the earth's figure is said to be spherical, we ought only to conceive it as being nearly so. It has been found in the last age to be flatted at both poles, so that its form is commonly resembled to that of a turnip. The cause of this swelling of the equator is ascribed to the greater rapidity of the motion with which the parts of the earth are there carried round; and which, consequently, endeavouring to fly off, act in opposition to central attraction. The twirling of a mop may serve as a homely illustration—which, as every one has seen, spreads and grows broader in the middle as it continues to be turned round.

As the earth receives light and motion from the sun, so it derives much of its warmth and power of vegetation from the same beneficent source. However, the different parts of the globe participate of these advantages in very different proportions, and accordingly put on very different appearances; a polar prospect, and a landscape at the equator, are as opposite in their appearances as in their situation.

The polar regions, that receive the solar beams in a very oblique direction, and that continue for one-half of the year in night, receive but few of the genial comforts that other parts of the world enjoy. Nothing can be more mournful or hideous than the picture which travellers present of those wretched regions. The ground, which is rocky and barren, rears itself in every place in lofty mountains and inaccessible cliffs, and meets the mariner's eye at even forty leagues from shore. These precipices, frightful in themselves, receive an additional horror from being constantly covered with ice and snow, which daily seems to accumulate, and to fill the valleys with increasing desolation. The few rocks and cliffs that are bare of snow look at a distance of a dark-brown colour, and quite naked. Upon a nearer approach, however, they are found replete with many different veins of coloured stone, here and there spread over with a little earth, and a scanty portion of grass and heath. The internal parts of the country are still more desolate and deterring. In wandering these solitudes, some plains appear covered with ice, that, at first glance, seems to promise the traveller an easy journey. But these are even more formidable and more unpassable than the

mountains themselves, being cleft with dreadful chasms, and every where abounding with pits that threaten certain destruction. The seas that surround these inhospitable coasts are still more astonishing, being covered with flakes of floating ice, that spread like extensive fields, or that rise out of the water like enormous mountains. These, which are composed of materials as clear and transparent as glass, assume many strange and phantastic appearances. Some of them look like churches or castles, with pointed turrets; some like ships in full sail; and people have often given themselves the fruitless toil to attempt piloting the imaginary vessels into harbour. There are still others that appear like large islands, with plains, valleys, and hills, which often rear their heads two hundred yards above the level of the sea; and although the height of these be amazing, yet their depth beneath is still more so; some of them being found to sink three hundred fathom under water.

The earth presents a very different appearance at the equator, where the sun-beams, darting directly downwards, burn up lighter soils into extensive sandy deserts, or quicken all the moister tracts with incredible vegetation. In these regions, almost all the same inconveniences are felt from the proximity of the sun, that in the former were endured from its absence. The deserts are entirely barren, except where they are found to produce serpents, and that in such quantities, that some extensive plains seem almost entirely covered with them.

It not unfrequently happens also that this dry soil, which is so parched and comminuted by the force of the sun, rises with the smallest breeze of wind; and the sands being composed of parts almost as small as those of water, they assume a similar appearance, rolling onward in waves like those of a troubled sea, and overwhelming all they meet with inevitable destruction. On the other hand, those tracts which are fertile teem with vegetation even to a noxious degree. The grass rises to such a height as often to require burning; the forests are impassable from underwoods, and so matted above, that even the sun, fierce as it is, can seldom penetrate. These are so thick as scarce to be extirpated; for the tops being so bound together by the climbing plants that grow round them, though a hundred should be cut at the bottom, yet not one would fall, as they mutually support each other. In these dark tangled forests, beasts of various kinds, insects in astonishing abundance, and serpents of surprising magnitude, find a quiet retreat from man, and are seldom disturbed except by each other.

In this manner the extremes of our globe seem equally unfitted for the comforts and conveniences of life; and although the imagination may find an awful pleasure in contemplating the frightful precipices of Greenland, or the luxurious verdure of Africa, yet true happiness can only be found in the more moderate climates, where the gifts of Nature may be enjoyed without incurring danger in obtaining them.

It is in the temperate zone, therefore, that all the arts of improving Nature, and refining upon happiness, have been invented: and this part of the earth is, more properly speaking, the theatre of natural history. Although there be millions of animals and vegetables in the unexplored forests under the line, yet most of these may for ever continue unknown, as curiosity is there repressed by surrounding danger. But it is otherwise in these delightful regions which we inhabit, and where this art has had its beginning. Among us there is scarce a shrub, a flower, or an insect, without its particular history; scarce a plant that could be useful which has not been propagated; nor a weed that could be noxious which has not been pointed out.

### CHAP. III.

#### A VIEW OF THE SURFACE OF THE EARTH.

When we take a slight survey of the surface of our globe, a thousand objects offer themselves, which, though long known, yet still demand our curiosity. The most obvious beauty that every where strikes the eye is the verdant covering of the earth, which is formed by a happy mixture of herbs and trees of various magnitudes and uses. It has been often remarked that no colour refreshes the sight so well as green; and it may be added, as a further proof of the assertion, that the inhabitants of those places where the fields are continually white with snow generally become blind long before the usual course of nature.

This advantage, which arises from the verdure of the fields, is not a little improved by their inequalities. There is scarce two natural landscapes that offer prospects entirely resembling each other; their risings and depressions, their hills and valleys, are never entirely the same, but always offer something new to entertain and refresh the imagination.

But to increase the beauties of the face of Nature, the landscape is enlivened by springs and lakes, and intersected by rivulets. These lend a brightness to the prospect, give motion and coolness to the air, and, what is much more important, furnish health and subsistence to animated Nature.

Such are the most obvious and tranquil objects that everywhere offer; but there are others of a more awful and magnificent kind—the mountain rising above the clouds, and topped with snow; the river pouring down its sides, increasing as it runs, and losing itself at last in the ocean; the ocean spreading its immense sheet of waters over one-half of the globe, swelling and subsiding at well-known intervals, and forming a communication between the most distant parts of the earth.

If we leave those objects that seem to be natural to our earth, and keep the same constant tenour, we are presented with the great irregularities of Nature. The burning mountain, the abrupt precipice, the unfathomable cavern, the headlong cataract, and the rapid whirlpool.

If we carry our curiosity a little further, and descend to the objects immediately below the surface of the globe, we shall there find wonders still as amazing. We first perceive the earth for the most part lying in regular beds or layers, every bed growing thicker in proportion as it lies deeper, and its contents more compact and heavy. We shall find, almost wherever we make our subterranean inquiry, an amazing number of shells that once belonged to aquatic animals. Here and there, at a distance from the sea, beds of oyster-shells, several yards thick, and many miles over; sometimes testaceous substances of various kinds on the tops of mountains, and often in the heart of the hardest marble. These, which are dug up by the peasants in every country, are regarded with little curiosity; for, being so very common, they are considered as substances entirely terrene. But it is otherwise with the inquirer after Nature, who finds them, not only in shape but in substance, every way resembling those that are bred in the sea; and he therefore is at a loss how to account for their removal.

Yet not one part of Nature alone, but all her productions and varieties, become the object of the speculative man's inquiry; he takes different views of Nature from the inattentive spectator, and scarce an appearance, how common soever, but affords matter for his contemplation: he inquires how and why the surface of the earth has come to have those risings and depressions which most men call natural; he demands in what manner the mountains were formed, and in what consists their uses; he asks from whence springs arise, and how rivers flow round the convexity of the globe; he enters into an

examination of the ebbings and flowings and the other wonders of the deep; he acquaints himself with the irregularities of Nature, and will endeavour to investigate their causes; by which, at least, he will become better versed in their history. The internal structure of the globe becomes an object of his curiosity; and although his inquiries can fathom but a very little way, yet, if possessed with a spirit of theory, his imagination will supply the rest. He will endeavour to account for the situation of the marine fossils that are found in the earth, and for the appearance of the different beds of which it is composed. These have been the inquiries that have splendidly employed many of the philosophers of the last and present age; and, to a certain degree, they must be serviceable. But the worst of it is, that, as speculations amuse the writer more than facts, they may be often carried to an extravagant length, and that time may be spent in reasoning upon Nature which might be more usefully employed in writing her history.

Too much speculation in natural history is certainly wrong; but there is a defect of an opposite nature that does much more prejudice, namely, that of silencing all inquiry, by alleging the benefits we receive from a thing, instead of investigating the cause of its production. If I enquire how a mountain came to be formed; such a reasoner, enumerating its benefits, answers, because God knew it would be useful. If I demand the cause of an earthquake, he finds some good produced by it, and alleges that as the cause. Thus such an inquirer has some ready reason for every appearance in Nature, which serves to swell his periods, and give splendour to his declamation: every thing about him is, on some account or other, declared to be good; and he thinks it presumptuous to scrutinize into its defects, or to endeavour to imagine how it might be better. Such writers, and there are many such, add very little to the advancement of knowledge; and it is finely remarked by Bacon, that the investigation of final causes in a barren study; and, like a virgin dedicated to the Deity, brings forth nothing. In fact, those men who want to compel every appearance and every irregularity in Nature into our service, and expatiate on their benefits, combat that very morality which they would seem to promote. God has permitted thousands of natural evils to exist in the world because it is by their intervention that man is capable of moral evil; and He has permitted that we should be subject to moral evil that we might do something to deserve eternal happiness, by showing that we had rectitude to avoid it

#### CHAP. IV.

##### A REVIEW OF THE DIFFERENT THEORIES OF THE EARTH.

Human invention has been exercised for several ages to account for the various irregularities of the earth. While those philosophers mentioned in the last chapter see nothing but beauty, symmetry, and order, there are others who look upon the gloomy side of Nature, enlarge on its defects, and seem to consider the earth on which they tread as one scene of extensive desolation. Beneath its surface they observe minerals and waters confusedly jumbled together; its different beds of earth irregularly lying upon each other; mountains rising from places that once were level; hills sinking into valleys; whole regions swallowed by the sea, and others again rising out of its bosom;—all these they suppose to be but a few of the changes that have been wrought in our globe; and they send out Imagination to describe it in its primeval state of beauty.

Of those who have written theories describing the

manner of the original formation of the earth, or accounting for its present appearances, the most celebrated are Burnet, Whiston, Woodward, and Buffon. As speculation is endless, so it is not to be wondered that all these differ from each other, and give opposite accounts of the several changes which they suppose our earth to have undergone. As the systems of each have had their admirers, it is in some measure incumbent upon the natural historian to be acquainted at least with their outlines; and, indeed, to know what others have even dreamed in matters of science is very useful, as it may often prevent us from indulging similar delusions ourselves, which we should never have adopted, but because we take them to be wholly our own. However, as entering into a detail of these theories is rather furnishing a history of opinions than things, I will endeavour to be as concise as I can.

The first who formed this amusement of earth-making into system was the celebrated Thomas Burnet, a man of polite learning and rapid imagination. His Sacred Theory, as he calls it, describing the changes which the earth has undergone, or shall hereafter undergo, is well known for the warmth with which it is imagined, and the weakness with which it is reasoned; for elegance of its style, and the meanness of its philosophy. "The earth," says he, "before the deluge, was very differently formed from what it is at present: it was at first a fluid mass; a chaos composed of various substances, differing both in density and figure: those which were most heavy sunk to the centre, and formed in the middle of our globe a hard solid body; those of a lighter nature remained next; and the waters, which were lighter still, swam upon its surface, and covered the earth on every side. The air, and all those fluids which were lighter than water, floated upon this also; and in the same manner encompassed the globe; so that between the surrounding body of waters and the circumambient air, there was formed a coat of oil, and other unctuous substances lighter than water. However, as the air was still extremely impure, and must have carried up with it many of those earthy particles with which it was once intimately blended, it soon began to defecate, and to deposit these particles upon the oily surface already mentioned, which, soon uniting together, the earth and oil formed that crust which soon became an habitable surface, giving life to vegetation and dwelling to animals."

This imaginary antediluvian abode was very different from what we see at present. "The earth was light and rich; and formed of a substance entirely adapted to the feeble state of incipient vegetation: it was an uniform plain, every where covered with verdure; without mountains, without seas, or the smallest inequalities. It had no difference of seasons, for its equator was in the plain of the ecliptic, or in other words, it turned directly opposite to the sun, so that it enjoyed one perpetual and luxuriant spring. However, this delightful face of Nature did not long continue the same, for, after a time, it began to crack and open in fissures; a circumstance which always succeeds when the sun dries away the moisture from rich or marshy situations. The crimes of mankind had been for some time preparing to draw down the wrath of Heaven; and they, at length, induced the Deity to defer repairing these breaches in Nature. Thus the chasms of the earth every day became wider, and, at length, they penetrated to the great abyss of waters; and the whole earth, in a manner, fell in. Then ensued a total disorder in the uniform beauty of the first creation, the terrene surface of the globe being broken down; as it sunk the waters gushed out into its place; the deluge became universal; all mankind, except eight persons, were punished with destruction, and their posterity condemned to toil upon the ruins of desolated Nature.

It only remains to mention the manner in which He relieves the earth from this universal wreck, which would

seem to be as difficult as even its first formation. "These great masses of earth falling into the abyss, drew down with them vast quantities also of air; and by dashing against each other, and breaking into small parts by the repeated violence of the shock, they, at length, left between them large cavities, filled with nothing but air. These cavities naturally offered a bed to receive the influent waters; and in proportion as they filled, the face of the earth became once more visible. The higher parts of its broken surface, now become the tops of the mountains, were the first that appeared; the plains soon after came forward, and at length the whole globe was delivered from the waters, except the places in the lowest situations; so that the ocean and the seas are still a part of the ancient abyss that have not had a place to return. Islands and rocks are fragments of the earth's former crust; kingdoms and continents are larger masses of its broken substance; and all inequalities that are to be found on the surface of the present earth, are owing to the accidental confusion into which both earth and waters were then thrown."

The next theorist was Woodward, who, in his *Essay towards a Natural History of the Earth*, which was only designed to precede a greater work, has endeavoured to give a more rational account of its appearances; and was, in fact, much better furnished for such an undertaking than any of his predecessors, being one of the most assiduous naturalists of his time. His little book, therefore, contains many important facts relative to natural history, although his system may be weak and groundless.

He begins by asserting that all terrene substances are disposed in beds of various natures, lying horizontally one over the other, somewhat like the coats of an onion; that they are replete with shells, and other productions of the sea; the shells being found in the deepest cavities, and on the tops of the highest mountains. From these observations, which are warranted by experience, he proceeds to observe, that these shells and extraneous fossils are not productions of the earth, but are all actual remains of those animals which they are known to resemble; that all the beds of the earth lie under each other, in the order, of their specific gravity; and that they are disposed as if they had been left there by subsiding waters. All these assertions he affirms with much earnestness, although daily experience contradicts him in some of them; particularly we find layers of stone often over the lightest soils, and the softest earth under the hardest bodies. However, having taken it for granted that all the layers of the earth are found in the order of their specific gravity, the lightest at the top, and the heaviest next the centre, he consequently asserts, and it will not improbably follow, that all the substances of which the earth is composed were once in an actual state of dissolution. This universal dissolution he takes to have happened at the time of the flood. He supposes that at that time a body of water, which was then in the centre of the earth, uniting with that which was found on the surface, so far separated the terrene parts as to mix together in one fluid mass; the contents of which afterwards sinking according to their respective gravities, produced the present appearances of the earth. Being aware, however, of an objection that fossil substances are not found dissolved, he exempts them from this universal dissolution, and, for that purpose, endeavours to show that the parts of animals have a stronger cohesion than those of minerals; and that, while even the hardest rocks may be dissolved, bones and shells may still continue entire.

So much for Woodward; but of all the systems which were published respecting the earth's formation, that of Whiston was most applauded and most opposed. Nor need we wonder; for being supported with all the parade of deep calculation, it awed the ignorant, and produced the approbation of such as would be thought

otherwise, as it implied a knowledge of abstruse learning, to be even thought capable of comprehending what the writer aimed at. In fact, it is not easy to divest it of its mathematical garb; but those who have had leisure, have found the result of our philosopher's reasoning to be thus. He supposes the earth to have been originally a comet; and he considers the history of the creation, as given us in scripture, to have its commencement just when it was taken by the hand of the Creator, to be more regularly placed as a planet in our solar system. Before that time, he supposes it to have been a globe without beauty or proportion; a world in disorders, subject to all the vicissitudes which comets endure; some of which have been found, at different times, a thousand times hotter than melted iron; at others, a thousand times colder than ice. These alternations of heat and cold, continually melting and freezing the surface of the earth, he supposes to have produced, to a certain depth, a chaos entirely resembling that described by the poets, surrounding the solid contents of the earth, which still continued unchanged in the midst, making a great burning globe of more than two thousand leagues in diameter. This surrounding chaos, however, was far from being solid; he resembles it to a dense though fluid atmosphere, composed of substances mingled, agitated, and shocked against each other; and in this disorder he describes the earth to have been just at the eve of creation.

But upon its orbit being then changed, when it was more regularly wheeled round the sun, every thing took its proper place; every part of the surrounding fluid then fell into a situation, in proportion as it was light or heavy. The middle, or central part, which always remained unchanged, still continued so, retaining a part of that heat which it received in its primeval approaches towards the sun; which heat, he calculates, may continue for about six thousand years. Next to this fell the heavier parts of the chaotic atmosphere which serve to sustain the lighter; but as in descending they could not entirely be separated from many watery parts with which they were intimately mixed, they drew down a part of these also with them; and these could not mount again after the surface of the earth was consolidated; they therefore surrounded the heavy first descending parts, in the same manner as these surround the central globe. Thus the entire body of the earth is composed most internally of a great burning globe; next which is placed a heavy terrene substance, that encompasses it; round which also is circumfused a body of water. Upon this body of waters the crust of earth on which we inhabit is placed; so that, according to him, the globe is composed of a number of coats, or shells, one within the other, all of different densities. The body of the earth being thus formed, the air, which is the lightest substance of all, surrounded its surface; and the beams of the sun darting through produced that light which, we are told, first obeyed the Creator's command.

The whole economy of the creation being thus adjusted, it only remained to account for the risings and depressions on the surface of the earth, with the other seeming irregularities of its present appearance. The hills and valleys are considered by him as formed by their pressing upon the internal fluid, which sustains the outward shell of earth, with greater or less weight; those parts of the earth which are heaviest sink into the subjacent fluid more deeply, and become valleys; those that are lightest rise higher upon the earth's surface, and are called mountains.

Such was the face of Nature before the deluge; the earth was then more fertile and populous than it is at present; the life of man and animals was extended to ten times its present duration; and all these advantages arose from the superior heat of the central globe, which ever since has been cooling. As its heat was then in its

full power, the genial principle was also much greater than at present; vegetation and animal increase were carried on with more vigour, and all Nature seemed teeming with the seeds of life. But these physical advantages were only productive of moral evil; the warmth which invigorated the body increased the passions and appetites of the mind; and as man became more powerful he grew less innocent. It was found necessary to punish his depravity; and all living creatures, except the fishes (who, living in a cold element, were not subject to a similitude of guilt), were overwhelmed by the deluge in universal destruction.

This deluge, which simple believers are willing to ascribe to a miracle, philosophers have long been desirous to account for by natural causes; they have proved that the earth could never supply from any reservoir towards its centre, nor the atmosphere by any discharge from above, such a quantity of water as would cover the surface of the globe to a certain depth over the tops of our highest mountains. Where, therefore, was all this water to be found? Whiston has found enough, and more than a sufficiency, in the tail of a comet; for he seems to allot comets a very active part in the great operations of Nature.

He calculates, with great seeming precision, the year, the month, and the day of the week on which this comet (which has paid the earth some visits since, though at a kinder distance) involved our globe in its tail. The tail he supposed to be a vaporous fluid substance, exhaled from the body of the comet by the extreme heat of the sun, and increasing in proportion as it approached that great luminary. It was in this that our globe was involved at the time of the deluge; and, as the earth still acted by its natural attraction, it drew to itself all the watery vapours which were in the comet's tail; and the internal waters being also at the same time let loose, in a very short space the tops of the highest mountains were laid under the deep.

The punishment of the deluge being thus completed, and all the guilty destroyed, the earth, which had been broken by the eruption of the internal waters, was also enlarged by the same; so that upon the comet's recess there was found room sufficient in the internal abyss for the recess of the superfluous waters; whither they all retired, and left the earth uncovered, but in some respects changed, particularly in its figure, which, from being round, was now become oblate. In this universal wreck of Nature Noah survived, by a variety of happy causes, to re-people the earth, and to give birth to a race of men slow in believing ill-imagined theories of the earth.

After so many theories of the earth, which had been published, applauded, answered, and forgotten, Mr. Buffon ventured to add one more to the number. This philosopher was, in every respect, better qualified than any of his predecessors for such an attempt, being furnished with more materials, having a brighter imagination to find new proofs, and a better style to clothe them in. However, if one so ill qualified as I am may judge, this seems the weakest part of his admirable work; and I could wish that he had been content with giving us facts instead of systems; that, instead of being a reasoner, he had contented himself with being merely a historian.

He begins his system by making a distinction between the first part of it and the last; the one being founded only on conjecture; the other depending entirely upon actual observation. The latter part of his theory may, therefore, be true, though the former should be found erroneous.

"The planets," says he, "and the earth among the number, might have been formerly (he only offers this as conjecture) a part of the body of the sun, and adherent to its substance. In this situation, a comet falling in upon that great body might have given it such a shock, and so shaken its whole frame, that some of its particles might have been driven off like streaming

sparkles from red hot iron; and each of these streams of fire, small as they were in comparison of the sun, might have been large enough to have made an earth as great, nay, many times greater than ours. So that in this manner the planets, together with the globe which we inhabit, might have been driven off from the body of the sun by an impulsive force: in this manner also they would continue to recede from it for ever, were they not drawn back by its superior power of attraction; and thus, by the combination of the two motions, they are wheeled round in circles.

"Being in this manner detached at a distance from the body of the sun, the planets, from having been at first globes of liquid fire, gradually became cool. The earth also having been impelled obliquely forward, received a rotatory motion upon its axis at the very instant of its formation, and this motion being greatest at the equator, the parts there acting against the force of gravity, they must have swollen out, and given the earth an oblate or flatted figure.

"As to its internal substance, our globe having once belonged to the sun, it continues to be an uniform mass of melted matter, very probably vitrified in its primeval fusion. But its surface is very differently composed. Having been in the beginning heated to a degree equal to, if not greater than what comets are found to sustain; like them it had an atmosphere of vapours floating round it, and which cooling by degrees, condensed and subsided upon its surface. These vapours formed, according to their different densities, the earth, the water, and the air; the heavier parts falling first, and the lighter remaining still suspended."

Thus far our philosopher is, at least, as much a system maker as Whiston or Burnet; and, indeed, he fights his way with great perseverance and ingenuity through a thousand objections that naturally arise. Having, at last, got upon the earth, he supposes himself on firmer ground, and goes forward with greater security. Turning his attention to the present appearance of things upon this globe, he pronounces from the view that the whole earth was at first under water. This water he supposes to have been the lighter parts of its former evaporations, which, while the earthy particles sunk downwards by their natural gravity, floated on the surface, and covered it for a considerable space of time.

"The surface of the earth," says he, "must have been in the beginning much less solid than it is at present; and, consequently, the same causes which at this day produce but very slight changes, must then, upon so complying a substance, have had very considerable effects. We have no reason to doubt but that it was then covered with the waters of the sea; and that those waters were above the tops of our highest mountains, since, even in such elevated situations, we find shells and other marine productions in very great abundance. It appears also that the sea continued for a considerable time upon the face of the earth: for as these layers of shells are found so very frequent at such great depths, and in such prodigious quantities, it seems impossible for these to have supported their numbers all alive at one time; so that they must have been brought there by successive depositions. These shells are also found in the bodies of the hardest rocks, where they could not have been deposited, all at once, at the time of the deluge, or at any such instant revolution; since that would be to suppose, that all the rocks in which they are found were at that instant in a state of dissolution, which would be absurd to assert. The sea, therefore, deposited them wheresoever they are now to be found, and that by slow and successive degrees.

"It will appear, also, that the sea covered the whole earth, from the appearance of its layers, which, lying regularly one above the other, seem all to resemble the sediment formed at different times by the ocean. Hence, by the irregular force of its waves, and its currents driv-

ing the bottom into sand-banks, mountains must have been gradually formed within this universal covering of waters; and these successively raising their heads above its surface must, in time, have formed the highest ridges of mountains upon land, together with continents, islands, and low grounds, all in their turns. This opinion will receive additional weight, by considering that in those parts of the earth where the power of the ocean is greatest, the inequalities on the surface of the earth are highest; the ocean's power is greatest at the equator, where its winds and tides are most constant; and, in fact, the mountains at the equator are found to be higher than in any other part of the world. The sea, therefore, has produced the principal changes in our earth; rivers, volcanoes, earthquakes, storms, and rain having made but slight alterations, and only such as have affected the globe to very inconsiderable depths."

This is but a very slight sketch of Mr. Buffon's Theory of the Earth—a theory which he has much more powerfully supported than happily invented; and it would be needless to take up the reader's time from the pursuit of truth in the discussion of plausibilities. In fact, a thousand questions might be asked this most ingenious philosopher which he would not find it easy to answer; but such is the lot of humanity, that a single Goth can in one day destroy the fabric which the Cæsars were employed an age in erecting. We might ask how mountains, which are composed of the most compact and ponderous substances, should be the first whose parts the sea began to remove? We might ask how fossil-wood is found deeper even than shells? which argues, that trees grew upon the places he supposes once to have been covered with the ocean. But we hope this excellent man is better employed than to think of gratifying the petulance of incredulity, by answering endless objections.

## CHAP. V.

### OF FOSSIL-SHELLS AND OTHER EXTRANEOUS FOSSILS.

We may affirm of Mr. Buffon that which has been said of the chymists of old; though he may have failed in attaining his principal aim—that of establishing a theory—yet he has brought together such a multitude of facts relative to the history of the earth and the nature of its fossil productions, that Curiosity finds ample compensation, even while it feels the want of conviction.

Before, therefore, I enter upon the description of those parts of the earth which seem more naturally to fall within the subject, it will not be improper to give a short history of those animal productions that are found in such quantities, either upon its surface or at different depths below it. They demand our curiosity; and indeed there is nothing in natural history that has afforded more scope for doubt, conjecture, and speculation. Whatever depths of the earth we examine, or at whatever distance within land we seek, we most commonly find a number of fossil-shells, which, being compared with others from the sea of known kinds, are found to be exactly of a similar shape and nature. They are found at the very bottom of quarries and mines, in the retired and inmost parts of the most firm and solid rocks, upon the tops of even the highest hills and mountains, as well as in the valleys and plains; and this not in one country alone, but in all places where there is any digging for marble, chalk, or any other terrestrial matters that are so compact as to fence off the external injuries of the air, and thus preserve these shells from decay.

These marine substances, so commonly diffused and so generally to be met with, were for a long time considered by philosophers as productions, not of the sea, but of the earth. "As we find that spars," said they, "always shoot into peculiar shapes, so these seeming

snail, cockle, and muscle shells are only sportive forms that Nature assumes amongst others of its mineral varieties; they have the shape of fish, indeed, but they have always been terrestrial substances."

With this plausible solution mankind were for a long time content; but upon closer inquiry they were obliged to alter their opinion. It was found that these shells had in every respect the property of animal, and not of mineral nature. They were found exactly of the same weight with their fellow shells upon shore. They answered all the chymical trials in the same manner as sea-shells do. Their parts, when dissolved, had the same appearance to view, the same smell and taste. They had the same effects in medicine when inwardly administered; and, in a word, were so exactly conformable to marine bodies, that they had all the accidental concretions growing to them (such as pearls, corals, and snail shells) which are found in shells just gathered on the shore. They were therefore, from these considerations, again given back to the sea; but the wonder was, how to account for their coming so far from their own natural element upon land.

As this naturally gave rise to many conjectures, it is not to be wondered that some among them have been very extraordinary. An Italian, quoted by Mr. Buffon, supposes them to have been deposited in the earth at the time of the Crusades, by the pilgrims who returned from Jerusalem; who, gathering them upon the sea-shore, in return carried them to their different places of habitation. But this conjecture seems to have but a very inadequate idea of their numbers. At Touraine, in France, more than a hundred miles from the sea, there is a plain of about nine leagues long, and as many broad, from whence the peasants of the country supply themselves with marl for manuring their lands. They seldom dig deeper than twenty feet, and the whole plain is composed of the same materials, which are shells of various kinds, without the smallest portion of earth between them. Here, then, is a large space, in which are deposited millions of tons of shells, which pilgrims could not have collected, though their whole employment had been nothing else. England is furnished with its beds, which, though not quite so extensive, yet are equally wonderful. Near Reading, in Berkshire, for many succeeding generations, a continued body of oyster-shells has been found through the whole circumference of five or six acres of ground. The foundation of these shells is a hard rocky chalk; and above this chalk the oyster-shells lie in a bed of green sand, upon a level, as high as can possibly be judged, and about two feet thick. These shells are in their natural state; but they are found also petrified, and almost in equal abundance, in all the Alpine rocks, in the Pyrenees, on the hills of France, England, and Flanders. Even in all quarries from whence marble is dug, if the rocks be split perpendicularly downwards, petrified shells and other marine substances will be plainly discerned.

About a quarter of a mile from the river Medway, in the county of Kent, after the taking off the coping of a piece of ground there, the workmen came to a blue marble, which continued for three feet and a half or more deep, and then beneath appeared a hard floor or pavement, composed of petrified shells crowded closely together. This layer was about an inch deep, and several yards over; and it could be walked upon as upon a beach. These stones of which it was composed (the describer supposes them to have always been stones) were either wreathed as snails, or bivalvular like cockles. The wreathed kinds were about the size of a hazel-nut, and were filled with a stony substance of the colour of marl; and they themselves, also, till they were washed, were of the same colour; but when cleaned, they appeared of the colour of bezoar, and of the same polish. After boiling in water they became whitish, and left a chalkiness upon the fingers.

In several parts of Asia and Africa travellers have observed these shells in great abundance. In the mountains of Castravan, which lie above the city Barut, they quarry out a white stone, every part of which contains petrified fishes in great numbers, and of surprising diversity. They also seem to continue in such preservation, that their fins, scales, and all the minutest distinctions of their make, can be perfectly discerned.

From all these instances, we may conclude that fossils are very numerous; and, indeed, independent of their situations, they afford no small entertainment to observe them as preserved in the cabinets of the curious. The variety of their kinds is astonishing. Most of the sea-shells which are known, and many others to which we are entirely strangers, are to be seen either in their natural state, or in various degrees of petrification. In the place of some we have mere spar, or stone, exactly expressing all the lineaments of animals, as having been wholly formed from them. For it has happened, that the shells dissolving by very slow degrees, and the matter having nicely and exactly filled all the cavities within, this matter, after the shells have perished, has preserved exactly and regularly the whole print of their internal surface. Of these there are various kinds found in our pits: many of them resembling those of our own shores: and many others that are only to be found on the coasts of other countries. There are some shells resembling those that are never stranded upon our coasts, but that always remain in the deep: and many more there are which we can assimilate with no shells in our pits, but also fishes and corals in great abundance; together with almost every sort of marine production.

It is extraordinary enough, however, that the common red coral, though so very frequent at sea, is scarce seen in the fossil world, nor is there any account of its having ever been met with. But to compensate for this, there are all the kinds of the white coral now known; and many other kinds of that substance with which we are acquainted. Of animals there are various parts; the vertebrae of whales, and the mouths of lesser fishes; these, with teeth also of various kinds, are found in the cabinets of the curious: where they receive long Greek names, which it is neither the intention nor the province of this work to enumerate. Indeed, few readers would think themselves much improved, should I proceed with enumerating the various classes of the Conicthyodontes, Polypleptoginglimi, or the Orthoceratites. These names, which mean no great matter when they are explained, may serve to guide in the furnishing the page of instructive history.

From all these instances we see in what abundance these petrefactions are to be found; and, indeed, Mr. Buffon (to whose accounts we added some) has not been sparing in the variety of his quotations concerning the places where they are mostly to be found. However, I am surprised that he should have omitted the mention of one which, in some measure more than any of the rest, would have much strengthened his theory. We are informed, by almost every traveller that has described the pyramids of Egypt, that one of them is entirely built of a kind of freestone, in which these petrified shells are found in great abundance. This being the case, it may be conjectured—as we have accounts of these pyramids among the earliest records of mankind, and of their being built so long before the age of Herodotus (who lived but fifteen hundred years after the flood) that even the Egyptian priests could tell neither the time nor the cause of their erection—I say it may be conjectured that they were erected but a short time after the flood. It is not very likely, therefore, that the marine substances found in one of them had time to be formed into a part of the solid stone, either during the deluge or immediately after it; and consequently their petrification must have been before that period. And this is the opinion Mr. Buffon has all along so strenu-

ously endeavoured to maintain—having given specious reasons to prove that such shells were laid in the beds where they are now found, not only before the deluge, but even antecedent to the formation of "man, at the time when the whole earth, as he supposes, was buried beneath a covering of waters.

But while there are many reasons to persuade us that these extraneous fossils have been deposited by the sea, there is one fact that will abundantly serve to convince us that the earth was habitable, if not inhabited, before these marine substances came to be thus deposited; for we find fossil-trees, which no doubt once grew upon the earth, as deep, and as much in the body of solid rocks, as these shells are found to be. Some of these fallen trees, also, have lain at least as long, if not longer, in the earth than the shells, as they have been found sunk deep in a marly substance composed of decayed shells and other marine productions. Mr. Buffon has proved that fossil-shells could not have been deposited in such quantities all at once by the flood; and I think, from the above instance, it is pretty plain that, however they were deposited, the earth was covered with trees before their deposition; and, consequently, that the sea could not have made a very permanent stay. How, then, shall we account for these extraordinary appearances in Nature? A suspension of all assent is certainly the first, although the most mortifying conduct. For my own part, were I to offer a conjecture—and all that has been said upon this subject is only conjecture—instead of supposing them to be the remains of animals belonging to the sea, I would consider them rather as bred in the numerous fresh-water lakes that, in primeval times, covered the face of uncultivated Nature. Some of these shells we know to belong to fresh waters; some can be assimilated to none of the marine shells now known: why, therefore, may we not as well ascribe the production of all to fresh waters where we do not find them, as we do that of the latter to the sea only where we never find them? We know that lakes, and lands also, have produced animals that are now no longer existing; why, therefore, might not these fossil productions be among the number? I grant that this is making a very harsh supposition; but I cannot avoid thinking that it is not attended with so many embarrassments as some of the former, and that it is much easier to believe that these shells were bred in fresh water, than that the sea had for a long time covered the tops of the highest mountains.

## CHAP. VI.

### OF THE INTERNAL STRUCTURE OF THE EARTH.

Having, in some measure, got free from the regions of conjecture, let us now proceed to a description of the earth as we find it by examination, and observe its internal composition, as far as it has been the subject of experience, or exposed to human inquiry. These inquiries, indeed, have been carried but to a very little depth below its surface; and even in that disquisition men have been conducted more by motives of avarice than of curiosity. The deepest mine (which is that at Cotteburg, in Hungary) reaches not more than three thousand feet deep; but what proportion does that bear to the depth of the terrestrial globe, down to the centre, which is above four thousand miles? All, therefore, that has been said of the earth, to a deeper degree, is merely fabulous or conjectural. We may suppose with one, that it is a globe of glass (Buffon); with another, a sphere of heated iron (Whiston); with a third, a great mass of waters (Burnet); and with a fourth, one dreadful volcano (Kircher). But let us, at the same time, show our consciousness that all these are but suppositions.

Upon examining the earth where it has been opened to any depth, the first thing that occurs is the different layers or beds of which it is composed—these all lying horizontally one over the other like the leaves of a book, and each of them composed of materials that increase in weight as they lie deeper. This is, in general, the disposition of the different materials where the earth seems to have remained unmolested; but this order is frequently inverted—and we cannot tell whether from its original formation or from accidental causes. Of different substances, thus disposed, the far greatest part of our globe consists, from its surface downwards to the greatest depths we ever dig or mine.

The first coat that is most commonly found at the surface is that light coat of blackish mold, which is by some called "garden-earth." With this the earth is everywhere invested, unless it be washed off by rains, or removed by some other external violence. This seems to have been formed from animal and vegetable bodies decaying, and thus turning into its substance. It also serves again as a store-house, from whence animal and vegetable nature are renewed; and thus are all vital blessings continued with unceasing circulation. This earth, however, is not to be supposed entirely pure, but is mixed up with much stony and gravelly matter from the layers lying immediately beneath it. It generally happens that the soil is fertile in proportion to the quantity that this purified mold bears to the gravelly mixture; and as the former predominates, so far is the vegetation upon it more luxuriant. It is this external covering that supplies man with all the true riches he enjoys. He may bring up gold and jewels from greater depths; but they are merely the toys of a capricious being—things upon which he has placed an imaginary value, and for which fools alone part with the more substantial blessings of life. "It is this earth," says Pliny, "that, like a kind mother, receives us at our birth, and sustains us when born. It is this alone, of all the elements around us, that is never found an enemy to man. The body of waters deluge him with rains, oppress him with hail, and drown him with inundations. The air rushes in storms, prepares the tempest, or lights up the volcano. But the earth, gentle and indulgent, ever subservient to the wants of man, spreads his walks with flowers and his table with plenty; returns with interest every good committed to her care; and, though she produces the poison, she still supplies the antidote; though constantly teased more to furnish the luxuries of man than his necessities, yet even to the last she continues her kind indulgence, and, when life is over, she piously covers his remains in her bosom."

This external and fruitful layer which covers the earth is, as was said, in a state of continual change. Vegetables, which are naturally fixed and rooted to the same place, receive their adventitious nourishment from the surrounding earth and water; animals, which change from place to place, are supported by these, or by each other. Both, however, having for a time enjoyed a life adapted to their nature, give back to the earth those spoils which they had borrowed for a short space, yet still to be quickened again into fresh existence. But the deposits they make are of very dissimilar kinds, and the earth is very differently enriched by their continuance. Those countries that have for a long time supported men and animals have been observed to become every day more barren; while, on the contrary, those desolate places in which vegetables only are abundantly produced are known to be possessed of amazing fertility. "In regions which are uninhabited," says Mr. Buffon, "where the forests are not cut down, and where animals do not feed upon the plants, the bed of vegetable earth is constantly increasing. In all woods, and even in those which are often cut, there is a layer of earth, five or six inches thick, which has been formed by the leaves, branches, and bark which fall and rot upon the ground.

I have frequently observed, on a Roman way that crosses Burgundy for a long extent, that there is a bed of black earth, of more than a foot thick, gathered over the stony pavement, on which several trees of a considerable size are supported. This I have found to be nothing else than an earth formed by decayed leaves and branches, which have been converted by time into a black soil. Now, as vegetables draw much more of their nourishment from the air and water than they do from the earth, it must follow that, in rotting upon the ground, they must give more to the soil than they have taken from it. Hence, therefore, in woods kept a long time without cutting, the soil below increases to a considerable depth; and such we actually find the soil in those American wilds where the forests have been undisturbed for ages. But it is otherwise where men and animals have long subsisted; for as they make a considerable consumption of wood and plants, both for firing and other uses, they take more from the earth than they return to it. It follows, therefore, that the bed of vegetable earth in an inhabited country must be always diminishing, and must at length resemble the soil of Arabia Petrea, and other provinces in the East, which, having been long inhabited, are now become plains of salt and sand, the fixed salt always remaining while the other volatile parts have flown away."

If from this external surface we descend deeper, and view the earth cut perpendicularly downwards, either in the banks of great rivers or steepy sea-shores; or, going still deeper, if we observe it in quarries or mines, we shall find its layers regularly disposed in their proper order. We must not expect, however, to find them of the same kind and thickness in every place, as they differ in different soils and situations. Sometimes marl is seen to be over sand, and sometimes under it. The most common disposition is, that under the first earth is found gravel or sand; then clay or marl, then chalk or coal, marbles, ores, sands, gravels—and thus an alternation of these substances, each growing more dense as it sinks deeper. The clay, for instance, found at the depth of a hundred feet, is usually more heavy than that found not far from the surface. In a well which was dug at Amsterdam, to the depth of two hundred and thirty feet, the following substances were found in succession:—Seven feet of vegetable earth, nine of turf, nine of soft clay, eight of sand, four of earth, ten of clay, four of earth, ten of sand, two of clay, four of white sand, one of soft earth, fourteen of sand, eight of clay mixed with sand, four of sea-sand mixed with shells, then a hundred and two feet of soft clay, and then thirty-one feet of sand.

In a well dug at Marly, to the depth of a hundred feet, Mr. Buffon gives us a still more exact enumeration of its layers of earth. "Thirteen of a reddish gravel, two of gravel mingled with a vitrifiable sand, three of slime, two of marl, four of marly stone, five of marl in dust mixed with vitrifiable sand, six of very fine vitrifiable sand, three of earthy marl, three of hard marl, one of gravel, one of eglantine, a stone of the hardness and grain of marble, one of gravelly marl, one of stony marl, two of a coarser kind still, one of vitrifiable sand mixed with fossil-shells, two of fine gravel, three of stony marl, one of coarse powdered marl, one of stone, calcinable like marble, three of grey sand, two of white sand, one of red sand streaked with white, eight of grey sand with shells, three of very fine sand, three of grit, four of red sand streaked with white, three of white sand, and fifteen of reddish vitrifiable sand."

In this manner the earth is everywhere found in beds over beds, and what is still remarkable, each of them, as far as it extends, always maintains exactly the same thickness. It is found, also, that, as we proceed to considerable depths, every layer grows thicker. Thus, in the adduced instances we might have observed that the last layer was fifteen feet thick; while most of the others were not above eight; and this might have gone much

deeper for aught we can tell, as before they got through it the workmen ceased digging.

These layers are sometimes very extensive, and often are found to spread over a space of some leagues in circumference. But it must not be supposed that they are uniformly continued over the whole globe without any interruption; on the contrary, they are ever, at small intervals, cracked through as it were by perpendicular fissures—the earth resembling, in this respect, the muddy bottom of a pond, from whence the water has been dried up by the sun, and thus gaping in several chinks, which descend in a direction perpendicular to its surface. These fissures are many times found empty, but oftener closed up with adventitious substances which the rain, or some other accidental causes, have conveyed to fill their cavities. Their openings are not less different than their contents—some being not above half an inch wide, some a foot, and some several hundred yards asunder. These last form those dreadful chasms that are to be found in the Alps, at the edge of which the traveller stands dreading to look down at the immeasurable gulf below. These amazing clefts are well known to such as have passed these mountains, where a chasm frequently presents itself several hundred feet deep, and as many over, at the edge of which the way lies. It often happens, also, that the road leads along the bottom, and then the spectator observes on each side frightful precipices several hundred yards above him, the sides of which correspond so exactly with each other, that they evidently seem torn asunder.

But these chasms to be found in the Alps are nothing to what Ovalle tells us are to be seen in the Andes. These amazing mountains, in comparison of which the former are but little hills, have their fissures in proportion to their greatness. In some places they are a mile wide, and deep in proportion; and there are some others that, running underground, in extent resemble a forest.

Of this kind also is that cavern called "Eldenhole," in Derbyshire; which, Dr. Plot tells us, was founded by a line of eight and twenty hundred feet, without finding the bottom, or meeting with water: and yet the mouth at the top is not above forty yards over. This immeasurable cavern runs perpendicularly downward; and the sides of it seem to tally so plainly as to show that they once were united. Those who come to visit the place generally procure stones to be thrown into its mouth; and these are heard, for several minutes, falling and striking against the sides of the cavern, producing a sound that resembles distant thunder, dying away as the stone goes deeper.

Of this kind also is that dreadful cavern described by Ælian, his account of which the reader may not have met with. "In the country of the Arrian Indians is to be seen an amazing chasm, which is called The Gulph of Pluto. The depth and the recesses of this horrid place are as extensive as they are unknown. Neither the natives, nor the curious who visit it, are able to tell how it first was made, or to what depths it descends. The Indians continually drive thither great multitudes of animals, more than three thousand at a time, of different kinds, sheep, horses, and goats; and, with an absurd superstition, force them into the cavity, from whence they never return. Their several sounds, however, are heard as they descend; the bleating of sheep, the lowing of oxen, and the neighing of horses, issuing up to the mouth of the cavern. Nor do these sounds cease, as the place is continually furnished with a fresh supply."

There are many more of these dreadful perpendicular fissures in different parts of the earth; with accounts of which Kircher, Gaffarellus, and others who have given histories of the wonders of the subterranean world, abundantly supplied us. The generality of readers, however, will consider them with less astonishment, when they are informed of their being common all over the earth; that in every field, in every quarry, these per-

pendicular fissures are to be found, either still gaping, or filled with matter that has accidentally closed their interstices. The inattentive spectator neglects the inquiry, but their being common is partly the cause that excites the philosophers attention to them; the irregularities of Nature he is often content to let pass unexamined; but when a constant and a common appearance presents itself, every return of the object is a fresh call to his curiosity; and the chink in the next quarry becomes as great a matter of wonder as the chasm in Eldenhole. Philosophers have long, therefore, endeavoured to find out the cause of these perpendicular fissures, which our own countrymen, Woodward and Ray, were the first that found to be so common and universal. Mr. Buffon supposes them to be cracks made by the sun, in drying up the earth immediately after its emersion from the deep. The heat of the sun is very probably a principal cause; but it is not right to ascribe to one only, what we find may be the result of many. Earthquakes, severe frosts, bursting waters, and storms tearing up the roots of trees, have in our own times produced them: and to this variety of causes we must, at present, be content to assign those that have happened before we had opportunities for observation

## CHAP. VII.

### OF CAVES AND SUBTERRANEAN PASSAGES THAT SINK, BUT NOT PERPENDICULARLY, INTO THE EARTH.

In surveying the subterranean wonders of the globe, besides those fissures that descend perpendicularly, we frequently find others that descend but a little way, and then spread themselves often to a great extent below the surface. Many of these caverns, it must be confessed, may be the production of art and human industry—retreats made to protect the oppressed or to shelter the spoiler. The famous labyrinth of Candia, for instance, is supposed to be entirely the work of art. Mr. Tournefort assures us that it bears the impression of human industry, and that great pains have been bestowed upon its formation. The stone-quarry of Maestricht is evidently made by labour: carts enter at its mouth and load within, then return and discharge their freight into boats that lie on the brink of the river Maese. This quarry is so large, that forty thousand people may take shelter in it; and in general serves for this purpose when armies march that way—becoming then an impregnable retreat to the people that live thereabout. Nothing can be more beautiful than this cavern when lighted up with torches; for there are thousands of square pillars, in large level walks, about twenty feet high, and all wrought with much neatness and regularity. In this vast grotto there is very little rubbish—which shows both the goodness of the stone and the carefulness of the workmen. To add to its beauty, there are also, in various parts of it, little pools of water for the convenience of the men and cattle. It is also remarkable that no droppings are seen to fall from the roof, nor are the walks any way wet under foot, except in cases of great rains, where the water gets in by the airshafts. The salt mines in Poland are still more spacious than these. Some of the catacombs, both in Egypt and Italy, are said to be very extensive. But no part of the world has a greater number of artificial caverns than Spain, which were made to serve as retreats to the Christians against the fury of the Moors, when the latter conquered that country. However, an account of the works of Art does not properly belong to a Natural History. It will be enough to observe, that though caverns be found in every country, far the greatest part of them have been fashioned only by the hand of Nature. Their size is found to be beyond the power of man to have effected,

and their forms but ill-appointed to the conveniences of a human habitation. In some places, indeed, we find mankind still make use of them as houses, particularly in those countries where the climate is very severe; but in general they are deserted by every race of meaner animals except the bat: these nocturnal, solitary creatures are the only inhabitants—and these only in such whose descent is sloping, or, at least, not directly perpendicular.

There is scarce a country in the world without its natural caverns; and many new ones are discovered every day. Of those in England, Oakley-hole, the Devil's-hole, and Penpark-hole, have been often described. The former, which lies on the south-side of Mendip-hills, within a mile of the town of Wells, is much resorted to by travellers. To conceive a just idea of this, we must imagine a precipice of more than a hundred yards high, on the side of a mountain which shelves away a mile above it. In this is an opening not very large, into which you enter, going along upon a rocky, uneven pavement, sometimes ascending, and sometimes descending. The roof as you advance grows higher, and in some places is fifty feet from the floor; in other places, however, it is so low, that a man must stoop to pass. It extends itself in length about two hundred yards; and from every part of the roof, and the floor, there are formed sparry concretions of various figures, which, by strong imaginations, have been likened to men, lions, and organs. At the farthest part of this cavern rises a stream of water, well stored with fish, large enough to turn a mill, and which discharges itself near the entrance.

Penpark-hole, in Gloucestershire, is almost as remarkable as the former. Captain Sturmer descended into this by a rope twenty-five fathoms perpendicular, and at the bottom found a very large vault in the shape of a horse-shoe. The floors consisted of a kind of white stone enamelled with lead ore, and the pendant rocks were glazed with spar. Walking forward on this stony pavement for some time, he came to a great river twenty fathoms broad and eight fathoms deep; and, having been informed that it ebbed and flowed with the sea, he remained in this gloomy abode for five hours, to make an exact observation. He did not find, however, any alteration whatsoever in its appearance. But his curiosity was ill requited, for it cost this unfortunate gentleman his life: immediately after his return he was seized with an unusual and violent head-ache, which threw him into a fever, of which he died soon after.

But of all the subterranean caverns now known, the grotto of Antiparos is the most remarkable, as well for its extent, as for the beauty of its sparry incrustations. This celebrated cavern was first discovered by one Magni, an Italian traveller, about a hundred years ago, at Antiparos, an inconsiderable island of the Archipelago. The account he gives of it is long and inflated, but upon the whole amusing. "Having been informed," says he, "by the natives of Paros, that in the little island of Antiparos, which lies about two miles from the former, of a gigantic statue that was to be seen at the mouth of a cavern in that place, it was resolved that we (the French consul and himself) should pay it a visit. In pursuance of this resolution, after we had landed on the island, and walked about four miles through the midst of beautiful plains and sloping woodlands, we at length came to a little hill, on the side of which yawned a most horrid cavern, that with its gloom at first struck us with terror, and almost repressed curiosity. Recovering the first surprise, however, we entered boldly; and had not proceeded above twenty paces when the supposed statue of the gaint presented itself to our view. We quickly perceived that what the ignorant natives had been terrified at as a giant, was nothing more than a sparry concretion, formed by the water dropping from the roof of the cave, and by degrees hardening into a

figure that their fears had formed into a monster. Incited by this extraordinary appearance, we were induced to proceed still farther, in quest of new adventures in this subterranean abode. As we proceeded, new wonders offered themselves; the spars, formed into trees and shrubs, presented a kind of petrified grove; some white, some green; and all receding in due perspective. They struck us with the more amazement, as we knew them to be mere productions of Nature, who, hitherto in solitude, had, in her playful moments, dressed the scene as if for her own amusement.

"But we had as yet seen but a few of the wonders of the place; and were introduced only into the portico of this amazing temple. In one corner of this half-illuminated recess, there appeared an opening of about three feet wide, which seemed to lead to a place totally dark, and that, one of the natives assured us, contained nothing more than a reservoir of water. Upon this we tried by throwing down some stones, which, rumbling along the sides of the descent for some time, the sound seemed at last quashed in a bed of water. In order, however, to be more certain, we sent in a Levantine mariner, who, by the promise of a good reward, with a flambeau in his hand, ventured into this narrow aperture. After continuing within it for about a quarter of an hour, he returned, carrying some beautiful pieces of white spar in his hand, which Art could neither imitate nor equal. Upon being informed by him that the place was full of these beautiful incrustations, I ventured in once more with him, for about fifty paces, anxiously and cautiously descending by a steep and dangerous way. Finding, however, that we came to a precipice which led into a spacious amphitheatre, if I may so call it, still deeper than any other part, we returned, and being provided with a ladder, flambeaux, and other things to expedite our descent, our whole company, man by man, ventured into the same opening, and, descending one after another, we at last saw ourselves all together in the most magnificent part of the cavern.

"Our candles being now all lighted up, and the whole place completely illuminated, never could the eye be presented with a more glittering or a more magnificent scene. The roof all hung with solid icicles, transparent as glass, yet solid as marble. The eye could scarce reach the lofty and noble ceiling; the sides were regularly formed with spars; and the whole presented the idea of a magnificent theatre, illuminated with an immense profusion of lights. The floor consisted of solid marble; and, in several places, magnificent columns, thorns, altars, and other objects appeared, as if Nature had designed to mock the curiosities of Art. Our voices, upon speaking or singing, were redoubled to an astonishing loudness; and upon the firing of a gun, the noise and reverberations were almost deafening. In the midst of this grand amphitheatre rose a concretion of about fifteen feet high, that in some measure resembled an altar.

"Below even this spacious grotto there seemed another cavern, down which I ventured with my former mariner, and descended about fifty paces by means of a rope. I at last arrived at a small spot of level ground, where the bottom appeared different from that of the amphitheatre, Being composed of soft clay, yielding to the pressure, and in which I thrust a stick to about six feet deep. In this, however, as above, numbers of the most beautiful crystals were formed, one of which particularly resembled a table. Upon our egress from this amazing cavern we perceived a Greek inscription upon a rock at the mouth, but so obliterated by time that we could not read it. It seemed to import that one Antipater, in the time of Alexander, had come thither; but whether he had penetrated into the depths of the cavern he does not think fit to inform us."

Such is the account of this beautiful scene as commu-

nicated in a letter to Kircher. We have another, and a more copious, description by Tournefort; but I have given the above, both because it was communicated by the first discoverer, and because it is a simple narrative of facts without any reasoning upon them. According to Tournefort's account, indeed, we might conclude, from the rapid growth of the spars in this grotto, that it must every year be growing narrower, and that it must in time be entirely choked up with them; but no such thing has happened hitherto, and the grotto at this day continues as spacious as we ever knew it.

This is not the place for an inquiry into the seeming vegetation of those stony substances with which this and almost every cavern are incrustated; it is enough to observe, in general, that they are formed by an accumulation of that little gritty matter which is carried thither by the waters, and which in time acquires the hardness of marble. What in this place more imports us to know is, how these amazing hollows in the earth came to be formed; and I think, in the three instances above mentioned, it is pretty evident that their excavation has been owing to water. These finding subterranean passages under the earth, and by long degrees hollowing the beds in which they flowed, the ground above them has slipped down closer to their surface, leaving the upper layers of the earth or stone still suspended—the ground which sinks upon the face of the waters forming the floor of the cavern; the ground, or rock that keeps suspended, forming the roof. And, indeed, there are but few of these caverns found without water, either within them, or near enough to point out their formation.

## CHAP. VIII.

### OF MINES, DAMPS, AND MINERAL VAPOURS.

The caverns which we have been describing generally carry us but a very little way below the surface of the earth: two hundred feet, at the utmost, is as much as the lowest of them is found to sink. The perpendicular fissures run much deeper, but few persons have been bold enough to venture down to their deepest recesses; and some few who have tried have been able to bring back no tidings of the place—for unfortunately they left their lives below. The excavations of art have conducted us much further into the bowels of the globe. Some mines in Hungary are known to be a thousand yards perpendicular downwards; and I have been informed, by good authority, of a coal-mine in the north of England a hundred yards deeper still.

It is beside our present purpose to inquire into the peculiar construction and contrivance of these, which more properly belong to the history of fossils. It will be sufficient to observe in this place, that as we descend into the mines the various layers of earth are seen as we have described them, and in some of these are always found the metals or minerals for which the mine has been dug. Thus frequently gold is found dispersed and mixed with clay and gravel; sometimes it is mixed with other metallic bodies, stones, or bitumens: and sometimes united with that most obstinate of all substances, platina, from which scarce any art can separate it. Silver is sometimes found quite pure, sometimes mixed with other substances and minerals. Copper is found in beds mixed with various substances—marbles, sulphurs, and pyrites. Tin (the ore of which is heavier than that of any other metal) is generally found mixed with every kind of matter. Lead is also equally common; and iron we well know can be extracted from all the substances upon earth.

The variety of substances which are thus found in the bowels of the earth in their native state have a very different appearance from what they are afterwards

taught to assume by human industry. The richest metals are very often less glittering and splendid than the most useless marcasites, and the basest ores are in general the most beautiful to the eye.

This variety of substances which composes the internal parts of our globe is productive of equal varieties, both above and below its surface. The combination of the different minerals with each other—the heats which arise from their mixture—the vapours they diffuse—the fires which they generate, or the colds which they sometimes produce, are all either noxious or salutary to man; so that in this great elaboratory of Nature a thousand benefits and calamities are forging of which we are wholly unconscious; and it is happy for us that we are so.

Upon our descent into mines of considerable depth, the cold seems to increase from the mouth as we descend; but after passing very low down, we begin by degrees to come into a warmer air, which sensibly grows hotter as we go deeper, till at last the labourers can scarce bear any covering as they continue working.

This difference in the air was supposed by Boyle to proceed from magazines of fire that lay nearer the centre, and that diffused their heat to the adjacent regions. But we now know that it may be ascribed to more obvious causes. In some mines, the composition of the earth all around is of such a nature, that upon the admission of water or air it frequently becomes hot, and often bursts out into eruptions. Besides this, as the external air cannot readily reach the bottom, or be renewed there, an observable heat is perceived below, without the necessity of recurring to the central heat for an explanation.

Hence, therefore, there are two principal causes of the warmth at the bottom of mines—the heat of the substances of which the sides are composed, and the want of renovation in the air below. Any sulphureous substance mixed with iron produces a very great heat by the admission of water. If, for instance, a quantity of sulphur be mixed with a proportionable share of iron filings, and both kneaded together into a soft paste with water, they will soon grow hot, and at last produce a flame. This experiment, produced by art, is very commonly effected within the bowels of the earth by Nature. Sulphurs and irons are intimately blended together, and want only the mixture of water or air to excite their heat; and this, when once raised, is communicated to all bodies that lie within the sphere of their operation. Those beautiful minerals called “marcasites” and “pyrites,” are often of this composition; and wherever they are found, either by imbibing the moisture of the air or having been by any means combined with water, they render the mine considerably hot.

The want of fresh air, also, at these depths is, as we have said, another reason for their being found much hotter. Indeed, without the assistance of art, the bottom of most mines would from this cause be insupportable. To remedy this inconvenience, the miners are often obliged to sink, at some convenient distance from the mouth of the pit where they are at work, another pit, which joins the former below, and which in Derbyshire is called an air-shaft. Through this the air circulates; and thus the workmen are enabled to breathe freely at the bottom of the place, which becomes, as Mr. Boyle affirms, very commodious for respiration, and also very temperate as to heat and cold. Mr. Locke, however, who has left us an account of the Mendip-mines, seems to present a different picture. “The descent into these is exceeding difficult and dangerous; for they are not sunk, like wells, perpendicularly, but as the crannies of the rocks happen to run. The constant method is to swing down by a rope placed under the arms, and clamber along by applying both feet and hands to the sides of the narrow passage. The air is conveyed into them through a little passage that runs along the sides from the top, where

they set up some turfs on the lee-side of the hole, to catch and force it down. These turfs being removed to the windy side, or laid over the mouth of the hole, the miners below presently want breath, and faint; and if sweet smelling flowers chance to be placed there, they immediately lose their fragrance, and stink like carrion." An air so very putrifying can never be very commodious for respiration.

Indeed, if we examine the complexion of most miners, we shall be very well able to form a judgment of the unwholesomeness of the place where they are confined. Their pale and sallow looks show how much the air is damaged by passing through those deep and winding ways, that are rendered humid by damps, or warmed with noxious exhalations. But although every mine is unwholesome, all are not equally so. Coal-mines are generally less noxious than those of tin; tin than those of copper; but of all, none are so dreadfully destructive as those of quicksilver. At the mines near the village of Idra, nothing can adequately describe the deplorable infirmities of such as fill the hospital there; emaciated and crippled, every limb contracted or convulsed, and some in a manner transpiring quicksilver at every pore. There was one man, says Dr. Pope, who was not in the mines above half a year, and yet whose body was so impregnated with this mineral, that, putting a piece of brass money in his mouth, or rubbing it between his fingers, it immediately became as white as if it had been washed over with quicksilver. In this manner all the workmen are killed sooner or later; first becoming paralytic, and then dying consumptive: and all this they sustain for the trifling reward of sevenpence a-day.

But these metallic mines are not so noxious from their own vapours as from those of the substances with which the ores are usually united, such as arsenic, cinnabar, bitumen, or vitriol. From the fumes of these, variously combined, and kept inclosed, are produced those various damps that put on so many dreadful forms, and are usually so fatal. Sometimes these noxious vapours are perceived by the delightful fragrance of their smell, somewhat resembling the pea-blossom in bloom, from whence one kind of damp has its name. The miners are not deceived, however, by its flattering appearances; but as they thus have timely notice of its coming, they avoid it while it continues, which is generally during the whole summer season. Another shows its approach by the burning of the candles, which seem to collect their flame into a globe of light, and thus gradually lessen, till they are quite extinguished. From this, also, the miners frequently escape; however, such as have the misfortune to be caught in it either swoon away and are suffocated, or slowly recover in excessive agonies. Here, also, is a third, called the fulminating damp, much more dangerous than either of the former, as it strikes down all before it like a flash of gunpowder, without giving any warning of its approach. But there is still another, more deadly than all the rest, which is found in those places where the vapour has been long confined, and has been by some accident set free. The air rushing out from thence always goes upon deadly errands; and scarce any escape to describe the symptoms of its operations.

Some colliers in Scotland, working near an old mine that had been long closed up, happened inadvertently to open a hole into it from the pit where they were then employed. By great good fortune they at that time perceived their error, and instantly fled for their lives. The next day, however, they were resolved to renew their work in the same pit, and eight of them ventured down, without any great apprehensions; but they had scarce got to the bottom of the stairs that led to the pit, but, coming within the vapour, they all instantly dropped down dead, as if they had been shot. Amongst these unfortunate poor men, there was one whose wife was informed he was stifled in the mine; and, as he hap-

pened to be next the entrance, she so far ventured down as to see where he lay. As she approached the place, the sight of her husband inspired her with a desire to rescue him, if possible, from that dreadful situation; though a little reflection might have shown her it was then too late. But nothing could deter her; she ventured forward, and had scarce touched him with her hand, when the damp prevailed, and the misguided but faithful creature fell dead by his side.

Thus, the vapours found beneath the surface of the earth are very various in their effects upon the constitution; and they are not less in their appearances. There are many kinds that seemingly are no way prejudicial to health, but in which the workmen breathe freely; and yet in these, if a lighted candle be introduced, they immediately take fire, and the whole cavern at once becomes one furnace of flame. In mines, therefore, subject to damps of this kind, they are obliged to have recourse to a very peculiar contrivance to supply sufficient light for their operations. This is by a great wheel, the circumference of which is beset with flints, which, striking against steels placed for that purpose at the extremity, a stream of fire is produced which affords light enough, and yet does not set fire to the mineral vapour.

Of this kind are the vapours of the mines about Bristol; on the contrary, in other mines, a single spark struck out from flint and steel would set the whole shaft in a flame. In such, therefore, every precaution is used to avoid a collision—the workmen making use only of wooden instruments in digging, and being cautious before they enter the mine to take out even the nails from their shoes. Whence this strange difference should arise—that the vapours of some mines catch fire with a spark, and others only with a flame—is a question that we must be content to leave in obscurity, till we know more of the nature both of mineral vapour and of fire. This only we may observe, that gunpowder will readily fire with a spark, but not with the flame of a candle; on the other hand, spirits of wine will ignite with the flame of a candle, but not with a spark. But even here the cause of this difference as yet remains a secret.

As, from this account of mines, it appears that the internal parts of the globe are filled with vapours of various kinds, it is not surprising that they should at different times reach the surface, and there put on various appearances. In fact, much of the salubrity and much of the unwholesomeness of climates and soils is to be ascribed to these vapours, which make their way from the bowels of the earth upwards, and refresh or taint the air with their exhalations. Salt mines, being naturally cold, send forth a degree of coldness to the external air to comfort and refresh it; on the contrary, metallic mines are known not only to warm it with their exhalations, but often to destroy all kinds of vegetation by their volatile corrosive fumes. In some mines dense vapours are plainly perceived issuing from their mouths, and sensibly warm to the touch. In some places, neither snow nor ice will continue on the ground that covers a mine; and over others the fields are found destitute of verdure. The inhabitants, also, are rendered dreadfully sensible of these subterraneous exhalations—being affected with such a variety of evils, proceeding entirely from this cause, that books have been professedly written upon this class of disorders.

Nor are these vapours which thus escape to the surface of the earth entirely unconfined, for they are frequently, in a manner, circumscribed to a spot; the grotto Del Cane, near Naples, is an instance of this; the noxious effects of which have made that cavern so very famous. This grotto, which has so much engaged the attention of travellers, lies within four miles of Naples, and is situated near a large lake of clear and wholesome water. Nothing can exceed the beauty of the landscape which this lake affords, being surrounded with hills covered with forests of the most beautiful verdure, and

the whole bearing a kind of amphitheatrical appearance. However, this region, beautiful as it appears, is almost entirely uninhabited—the few peasants that necessity compels to reside there looking quite consumptive and ghastly, from the poisonous exhalations that rise from the earth. The famous grotto lies on the side of a hill, near which place a peasant resides, who keeps a number of dogs for the purpose of showing the experiment to the curious. These poor animals always seem perfectly sensible of the approach of a stranger, and endeavour to get out of the way; however, their attempts being perceived, they are taken and brought to the grotto—the noxious effects of which they have so frequently experienced. Upon entering this place, which is a little cave, or hole rather, dug into the hill, about eight feet high, and twelve feet long, the observer can see no visible marks of its pestilential vapour; only to about a foot from the bottom, the wall seems to be tinged with a colour resembling that which is given by stagnant waters. When the dog, this poor philosophical martyr, as some have called him, is held above this mark, he does not seem to feel the smallest inconvenience; but when his head is thrust down lower, he struggles to get free for a little; but in the space of four or five minutes he seems to lose all sensation, and is taken out seemingly without life. Being plunged into the neighbouring lake he quickly recovers, and is permitted to run home, seemingly without the smallest injury.

This vapour, which thus for a time suffocates, is of the humid kind, as it extinguishes a torch and sullies a looking-glass; but there are other vapours perfectly inflammable, and that only require the approach of a candle to set them blazing. Of this kind was the burning well at Brosely, which is now stopped up; the vapour of which, when a candle was brought within about a foot of the surface of the water, caught flame like spirits of wine, and continued blazing for several hours after. Of this kind, also, are the perpetual fires in the kingdom of Persia. In that province where the worshippers of fire hold their chief mysteries, the whole surface of the earth, for some extent, seems impregnated with inflammable vapours. A reed stuck into the ground continues to burn like a flambeau; a hole made beneath the surface of the earth instantly becomes a furnace, answering all the purposes of a culinary fire. There they make lime by merely burying the stones in the earth, and watch with veneration the appearances of a flame that has not been extinguished for time immemorial. How different are men in various climates! This deluded people worship the vapours as a deity, which, in other parts of the world, are considered as one of the greatest evils.

## CHAP. IX.

### OF VOLCANOES AND EARTHQUAKES.

Mines and caverns, as we have said, reach but a very little way under the surface of the earth, and we have hitherto had no opportunities of exploring farther. Without all doubt, the wonders that are still unknown surpass those that have been represented, as there are depths of thousands of miles which are hidden from our inquiry. The only tidings we have from those unfathomable regions are by means of volcanoes—those burning mountains that seem to discharge their materials from the lowest abysses of the earth. A volcano may be considered as a cannon of immense size, the mouth of which is often near two miles in circumference. From this dreadful aperture are discharged torrents of flame and sulphur, and rivers of melted metal. Whole clouds of smoke and ashes, with rocks of enormous size, are discharged to many miles distance; so that the force

of the most powerful artillery is out as a breeze agitating a feather in comparison. In the deluge of fire and melted matter which runs down the sides of the mountain, whole cities are sometimes swallowed up and consumed. Those rivers of liquid fire are sometimes two hundred feet deep, and, when they harden, frequently form considerable hills. Nor is the danger of these confined to the eruption only; the force of the internal fire, struggling for vent, frequently produces earthquakes through the whole region where the volcano is situated. So dreadful have been these appearances, that men's terrors have added new horrors to the scene, and they have regarded as prodigies what we know to be the result of natural causes. Some philosophers have considered them as vents communicating with the fires of the centre, and the ignorant as the mouths of hell itself. Astonishment produces fear, and fear superstition; the inhabitants of Iceland believe the bellowings of Hecla are nothing else but the cries of the damned, and that its eruptions are contrived to increase their tortures.

But if we regard this astonishing scene of terror with a more tranquil and inquisitive eye, we shall find that these conflagrations are produced by very obvious and natural causes. We have already been apprised of the various mineral substances in the bottom of the earth, and their aptness to burst out into flames. Marcasites and pyrites in particular, by being humified with water or air, contract this heat, and often endeavour to expand with irresistible explosion. These, therefore, being lodged in the depths of the earth or the bosom of mountains, and being either washed by the accidental influx of waters below or fanned by air, insinuating itself through perpendicular fissures from above, take fire a first by only heaving in earthquakes, but at length by bursting through every obstacle, and making their dreadful discharge in a volcano.

These volcanoes are found in all parts of the earth. In Europe there are three that are very remarkable—*Ætna* in Sicily, *Vesuvius* in Italy, and *Hecla* in Iceland. *Ætna* has been a volcano for ages immemorial. Its eruptions are very violent, and its discharge has been known to cover the earth sixty-eight feet deep. In the year 1537, an eruption of this mountain produced an earthquake through the whole island for twelve days, overturned many houses, and at last formed a new aperture, which overwhelmed all within five leagues round. The cinders thrown up were driven even into Italy, and its burnings were seen at Malta at the distance of sixty leagues. "There is nothing more awful," says Kircher, "than the eruptions of this mountain, nor nothing more dangerous than attempting to examine its appearances, even long after the eruption has ceased. As we attempt to clamber up its steep sides, every step we take upward the feet sink back half way. Upon arriving near the summit, ashes and snow, with an ill-assorted conjunction, present nothing but objects of desolation. Nor is this the worst, for, as all places are covered over, many caverns are entirely hidden from the sight, into which if the inquirer happens to fall, he sinks to the bottom, and meets inevitable destruction. Upon coming to the edge of the great crater, nothing can sufficiently represent the tremendous magnificence of the scene. A gulf two miles over, and so deep that no bottom can be seen; on the sides pyramidal rocks starting out between apertures that emit smoke and flame; all this accompanied with a sound that never ceases, louder than thunder, strikes the bold with horror, and the religious with veneration for Him that has power to control its burnings."

In the descriptions of *Vesuvius* or *Hecla*, we shall find scarce anything but a repetition of the same terrible objects, but rather lessened, as these mountains are not so large as the former. The crater of *Vesuvius* is but a mile across, according to the same author; whereas that of *Ætna* is two miles. On this particular, however, we

must place no dependence, as these caverns every day alter—being lessened by the mountains sinking in at one eruption, and enlarged by the fury of another. It is not one of the least remarkable particulars respecting Vesuvius, that Pliny, the naturalist, was suffocated in one of its eruptions; for, his curiosity impelling him too near, he found himself involved in smoke and cinders when it was too late to retire—and his companions hardly escaped to give an account of the misfortune. It was in that dreadful eruption that the city of Herculaneum was overwhelmed, the ruins of which have been lately discovered at sixty feet distance below the surface, and (what is still more remarkable) forty feet below the bed of the sea. One of the most remarkable eruptions of this mountain was in the year 1707, which is finely described by Valetta—a part of whose description I shall beg leave to translate.

“Toward the latter end of summer, in the year 1707, the mount Vesuvius, that had for a long time been silent, now began to give some signs of commotion. Little more than internal murmurs at first were heard, which seemed to contend within the lowest depths of the mountain; no flame, nor even any smoke, was as yet seen. Soon after, some smoke appeared by day and a flame by night, which seemed to brighten all the country. At intervals, also, it shot off substances with a sound much like that of artillery, but which, even at so great a distance as we were at, infinitely exceeded it in greatness. Soon after it began to throw up ashes, which, becoming the sport of the winds, fell at great distances, and some many miles. To this succeeded showers of stones, which killed many inhabitants of the valley, and made dreadful ravage among the cattle. Soon after a torrent of burning matter began to roll down the sides of the mountain, at first with a slow and gentle motion, but soon with increased celerity. The matter thus poured out, when cold, seemed upon inspection to be of vitrified earth, the whole united into a mass of more than stony hardness. But what was particularly observable was, that upon the whole surface of these melted materials a light, spongy stone seemed to float, while the lower body was of the hardest substance, of which our roads are usually made. Hitherto there were no appearances but what had been often remarked before; but on the third or fourth day seeming flashes of lightning were shot forth from the mouth of the mountain, with a noise far exceeding the loudest thunder. These flashes, in colour and brightness, resembled what we usually see in tempests, but they assumed a more twisted and serpentine form. After this followed such clouds of smoke and ashes, that the whole city of Naples, in the midst of the day, was involved in nocturnal darkness, and the nearest friends were unable to distinguish each other in this frightful gloom. If any person attempted to stir without torch-light he was obliged to return, and every part of the city was filled with supplications and terror. At length, after a continuance of some hours, about one o'clock at midnight, the wind blowing from the north, the stars began to be seen; the heavens, although it was night, began to grow brighter; and the eruptions, after a continuance of fifteen days, began to lessen. The torrent of melted matter was seen to extend from the mountain down to the shore; the people began to return to their former dwellings, and the whole face of Nature to resemble its former appearance.”

The famous Bishop Berkley gives an account of one of these eruptions in a manner something different from the above. “In the year 1717, in the middle of April, with much difficulty I reached the top of Mount Vesuvius, in which I saw a vast aperture full of smoke, which hindered me from seeing its depth and figure. I heard within that horrid gulf certain extraordinary sounds, which seemed to proceed from the bowels of the mountain—a sort of murmuring, sighing, dashing sound; and, between whiles, a noise like that of thunder or

cannon, with a clattering like that of tiles falling from the tops of houses into the streets. Sometimes, as the wind changed, the smoke grew thinner, discovering a very ruddy flame, and the circumference of the crater streaked with red and several shades of yellow. After an hour's stay, the smoke, being moved by the wind, gave us short and partial prospects of the great hollow, in the flat bottom of which I could discern two furnaces almost contiguous—that on the left seeming about three yards over, glowing with ruddy flame, and throwing up red hot stones with a hideous noise, which, as they fell back, caused the clattering already noticed. May 8, in the morning, I ascended the top of Vesuvius a second time, and found a different face of things. The smoke, ascending upright, gave a full prospect of the crater, which, as I could judge, was about a mile in circumference, and a hundred yards deep. A conical mount had been formed since my last visit in the middle of the bottom, which I could see was made by the stones, thrown up and fallen back again into the crater. In this new hill remained the two furnaces already mentioned: the one was seen to throw up every three or four minutes, with a dreadful sound, a vast number of red hot stones, at least three hundred feet higher than my head, as I stood upon the brink; but as there was no wind, they fell perpendicularly back from whence they had been discharged. The other was filled with red hot liquid matter, like that in the furnace of a glass-house, raging and working like the waves of the sea, with a short, abrupt noise. This matter would sometimes boil over, and run down the side of the conical hill, appearing at first red hot, but changing colour as it hardened and cooled. Had the wind blown in our faces, we had been in no small danger of stifling by the sulphureous smoke, or being killed by the masses of melted materials that was shot from the bottom; but as the wind was favourable I had an opportunity of surveying this amazing scene for above an hour and a half together. On the 5th of June, after a horrid noise, the mountain was seen at Naples to work over; and about three days after its thunders were renewed so, that not only the windows in the city, but all the houses shook. From that time it continued to overflow, and sometimes at night were seen columns of fire shooting upwards from its summit. On the 20th, when all was thought to be over, the mountain again renewed its terrors, roaring and raging most violently. One cannot form a juster idea of the noise, in the most violent fits of it, than by imagining a mixed sound made up of the raging of a tempest, the murmur of a troubled sea, and the roaring of thunder and artillery, confused together. Though we heard this at the distance of twelve miles, yet it was terrible. I therefore resolved to approach nearer to the mountain; and, accordingly, three or four of us got into a boat, and were set ashore at a little town situated at the foot of the mountain. From thence we rode about four or five miles before we came to the torrent of fire that was descending from the side of the volcano; and here the roaring grew exceeding loud and terrible as we approached. I observed a mixture of colours in the cloud above the crater—green, yellow, red, blue. There was likewise a ruddy dismal light in the air, over the tract where that burning river flowed. These circumstances, set off and augmented by the horrors of the night, made a scene the most uncommon and astonishing I ever saw, which still increased as we approached the burning river. Imagine a vast torrent of liquid fire, rolling from the top down the side of the mountain, and with irresistible fury bearing down and consuming vines, olives, and houses, and divided into different channels, according to the inequalities of the mountain. The largest stream seemed half a mile broad at least, and five miles long. I walked so far before my companions up the mountain, along the side of the river of fire, that I was obliged to retire in great haste, the

sulphureous steam having surprised me, and almost taken away my breath. During our return, which was about three o'clock in the morning, the roaring of the mountain was heard all the way, and we observed it throwing up huge spouts of fire and burning stones, which, falling, resembled the stars in a rocket. Sometimes I observed two or three distinct columns of flame, and sometimes one only, which was large enough to fill the whole crater. These burning columns and fiery stones seemed to be shot a thousand feet perpendicular above the summit of the volcano; and in this manner the mountain was raging for six or eight days after. On the 18th of the same month the whole appearance ended, and the mountain remained perfectly quiet, without any visible smoke or flame."—[The annexed engraving represents an eruption which took place Aug. 2 and 3, 1847.]

The matter which is found to roll down from the mouth of all volcanoes in general resembles the dross that is thrown from a smith's forge. But it is different, perhaps, in various parts of the globe; for, as we have already said, there is not a quarter of the world that has not its volcanoes. In Asia, particularly in the islands of the Indian Ocean, there are many. One of the most famous is that of Albours, near Mount Taurus, the summit of which is continually on fire, and covers the whole adjacent country with ashes. In the island of Ternate there is a volcano which, some travellers assert, burns most furiously in the times of the equinoxes, because of the winds which then contribute to increase the flames. In the Molucca Islands there are many burning mountains; they are also seen in Japan, and the islands adjacent; and in Java and Sumatra, as well as in other of the Philippine Islands. In Africa there is a cavern, near Fez, which continually sends forth either smoke or flames. In the Cape de Verde Islands, one of them, called the Island del Fuego, continually burns; and the Portuguese, who frequently attempted a settlement there, have as often been obliged to desist. The Peak of Teneriffe is, as everybody knows, a volcano that seldom desists from eruptions. But of all parts of the earth America is the place where those dreadful irregularities of Nature are the most conspicuous. Vesuvius, and *Ætna* itself, are but mere fire-works in comparison to the burning mountains of the Andes, which, as they are the highest mountains in the world, so also are they the most formidable for their eruptions. The mountain of Arequipa, in Peru, is one of the most celebrated; Tarassá and Malahallo are very considerable; but that of Cotopaxi, in the province of Quito, exceeds anything we have hitherto read or heard of. The mountain of Cotopaxi, as described by Ulloa, is more than three miles perpendicular from the sea; and it became a volcano at the time of the Spaniards' first arrival in that country. A new eruption happened in the year 1743, having been some days preceded by a continual roaring in its bowels. The sound of one of these mountains is not, like that of the volcanoes in Europe, confined to a province, but is heard at 150 miles distance. "An aperture was made," says Ulloa, "in the summit of this immense mountain, and three more, about equal heights, near the middle of its declivity, which was at that time buried under prodigious masses of snow. The ignited substances ejected on that occasion, mixed with an immense quantity of ice and snow melting amidst the flames, were carried down with such astonishing rapidity, that in an instant the valley from Callo to Latacunga was overflowed; and besides its ravages in bearing down the houses of the Indians and other poor inhabitants, great numbers of people lost their lives. The river of Latacunga was the channel of this terrible flood, till, being too small for receiving such a prodigious current, it overflowed the adjacent country, like a vast lake near the town, and carried away all the buildings within its reach. The inhabitants retired into a spot of higher ground behind the town,

of which those parts which stood within the limits of the current were totally destroyed. The dread of still greater devastations did not subside for three days; during which the volcano ejected cinders, while torrents of melted ice and snow poured down its sides. The eruption lasted several days, and was accompanied with terrible roarings of the wind, rushing through the volcano, still louder than the former rumblings in its bowels. At last all was quiet—neither fire nor smoke to be seen nor noise to be heard; till, in the ensuing year, the flames again appeared with recruited violence, forcing their passage through several other parts of the mountain, so that in clear nights the flames, being reflected by the transparent ice, formed an awfully magnificent illumination."

Such is the appearance and the effect of those fires which proceed from the more inward recesses of the earth; for that they generally come from deeper regions than man has hitherto explored I cannot avoid thinking, contrary to the opinion of Mr. Buffon, who supposes them rooted but a very little way below the bed of the mountain. "We can never suppose," says this great naturalist, "that these substances are ejected from any great distance below, if we only consider the great force already required to fling them up to such vast heights above the mouth of the mountain; if we consider the substances thrown up, which we shall find upon inspection to be the same with those of the mountain below; if we take into our consideration that air is always necessary to keep up the flame; but, most of all, if we attend to one particular circumstance—which is, that if these substances were exploded from a vast depth below, the same force required to shoot them up so high would act against the sides of the volcano, and tear the whole mountain in pieces." To all this specious reasoning particular answers might easily be given, as that the length of the funnel increases the force of the explosion; that the sides of the funnel are actually often burst with the great violence of the flame; that air may be supposed at depths at least as far as the perpendicular fires descend. But the best answer is a well-known fact—namely, that the quantity of matter discharged from *Ætna* alone is supposed, upon a moderate computation, to exceed twenty times the original bulk of the mountain. The greatest part of Sicily seems covered with its eruptions. The inhabitants of Catania have found, at the distance of several miles, streets and houses sixty feet deep, overwhelmed by the lava or matter it has discharged. But what is still more remarkable, the walls of these very houses have been built of materials evidently thrown up by the mountain. The inference from all this is very obvious—that the matter thus exploded cannot belong to the mountain itself, otherwise it would have been quickly consumed; it cannot be derived from moderate depths, since its amazing quantity evinces that all the places near the bottom must have long since been exhausted; nor can it have an extensive and, if I may so call it, a superficial spread, for then the country would be quickly undermined; it must, therefore, be supplied from the deeper regions of the earth—those undiscovered tracts where the Deity performs his wonders in solitude, satisfied with self-approbation!

## CHAP. X.

### OF EARTHQUAKES.

Having given the theory of volcanoes, we have, in some measure, given also that of earthquakes. They both seem to proceed from the same cause, only with this difference, that the fury of the volcano is spent in the eruption, that of an earthquake spreads wider, and acts more fatally by being confined. The volcano only

affrights a province, earthquakes have laid whole kingdoms in ruin.

Philosophers have taken some pains to distinguish between the various kinds of earthquakes, such as the tremulous, the pulsative, perpendicular, and the inclined; but these are rather the distinctions of art than of Nature, mere accidental differences arising from the situation of the country or of the cause. If, for instance, the confined fire acts directly under a province or a town, it will heave the earth perpendicularly upward, and produce a perpendicular earthquake. If it acts at a distance, it will raise that tract obliquely, and thus the inhabitants will perceive an inclined one.

Nor does it seem to me that there is much greater reason for Mr. Buffon's distinction of earthquakes. One kind of which he supposes to be produced by fire in the manner of volcanoes, and confined to but a very narrow circumference. The other kind, he ascribes to the struggles of confined air, expanded by heat in the bowels of the earth, and endeavouring to get free. For how do these two causes differ? Fire is an agent of no power whatsoever without air. It is the air, which being at first compressed, and then dilated in a cannon, that drives the ball with such force. It is the air struggling for vent in a volcano that throws up its contents to such vast heights. In short, it is the air confined in the bowels of the earth, acquiring elasticity by heat, that produces all those appearances which are generally ascribed to the operation of fire. When, therefore, we are told that there are two causes of earthquakes, we only learn that a greater or smaller quantity of heat produces those terrible effects; for air is the only active perator in either.

Some philosophers, however, have been willing to give the air as great a share in producing these terrible effects as they could; and, magnifying its powers, have called in but a very moderate degree of heat to put it in action. Although experience tells us that the earth is full of inflammable materials, and that fires are produced wherever we descend; although it tells us that those countries where there are volcanoes are most subject to earthquakes, yet they step out of their way, and so find a new solution. These only allow but just heat enough to produce the most dreadful phenomena, and, backing their assertions with long calculations, give theory an air of demonstration. Mr. Amontons has been particularly sparing of the internal heat in this respect; and has shown, perhaps accurately enough, that a very moderate degree of heat may suffice to give the air amazing powers of expansion.

It is amazing enough, however, to trace the progress of a philosophical fancy let loose in imaginary speculations. They run thus: "A very moderate degree of heat may bring the air into a condition capable of producing earthquakes; for the air, at the depth of forty-three thousand five hundred and twenty-eight fathom below the surface of the earth, becomes almost as heavy as quicksilver. This, however, is but a very slight depth in comparison of the distance to the centre, and is scarce a seventieth part of the way. The air, therefore, at the centre, must be infinitely heavier than mercury, or any body that we know of. This granted, we shall take something more, and say that it is very probable there is nothing but air at the centre. Now let us suppose this air heated, by some means, even to the degree of boiling water, as we have proved that the density of the air is here very great, its elasticity must be in proportion: a heat, therefore, which at the surface of the earth would have produced but a slight expansive force, must at the centre produce one very extraordinary, and, in short, be perfectly irresistible. Hence this force may, with great ease, produce earthquakes; and, if increased, it may convulse the globe; it may (by only adding figures enough to the calculation) destroy the solar system, and even the fixed stars themselves." These reveries gene-

rally produce nothing; for, as I have ever observed, increased calculations, while they seem to tire the memory give the reasoning faculty perfect repose.

However, as earthquakes are the most formidable ministers of Nature, it is not to be wondered that a multitude of writers have been curiously employed in their consideration. Woodward has ascribed the cause to a stoppage of the waters below the earth's surface by some accident. These being thus accumulated, and yet acted upon by fires, which he supposes still deeper, both contribute to heave up the earth upon their bosom. This, he thinks, accounts for the lakes of water produced in an earthquake, as well as for the fires that sometimes burst from the earth's surface upon those dreadful occasions. There are others still who have supposed that the earth may be itself the cause of its own convulsions. "When," say they, "the roots or basis of some large tract is worn away by a fluid underneath, the earth sinking therein, its weight occasions a tremor of the adjacent parts, sometimes producing a noise, and sometimes an inundation of water." Not to tire the reader with a history of opinions instead of facts, some have ascribed them to electricity, and some to the same causes that produce thunder.

It would be tedious, therefore, to give all the various opinions that have employed the speculative upon this subject. The activity of the internal heat seems alone sufficient to account for every appearance that attends these tremendous irregularities of Nature. To conceive this distinctly, let us suppose at some vast distance under the earth large quantities of inflammable matter, pyrites, bitumens, and marcasites disposed, and only waiting for the aspersion of water or the humidity of the air to put their fires in motion: at last this dreadful mixture arrives; waters find their way into those depths through the perpendicular fissures; or air insinuates itself through the same minute apertures: instantly new appearances ensue: those substances, which for ages before lay dormant, now conceive new apparent qualities: they grow hot, produce new air, and only want room for expansion. However, the narrow apertures by which the air or water had at first admission are now closed up; yet as new air is continually generated as the heat every moment gives this air new elasticity, it at length bursts and dilates all round; and, in its struggles to get free, throws all above it into similar convulsions. Thus an earthquake is produced, more or less extensive, according to the depth or the greatness of the cause.

But before we proceed with the causes, let us take a short view of the appearances which have attended the most remarkable earthquakes. By these we shall see how far the theorist corresponds with the historian. The greatest we find in antiquity is that mentioned by Pliny, in which twelve cities in Asia Minor were swallowed up in one night: he tells us also of another, near the lake Thrasymene, which was not perceived by the armies of the Carthaginians and Romans, that were then engaged near the lake, although it shook the greatest part of Italy. In another place he gives the following account of an earthquake of an extraordinary kind. "When Lucius Marcus and Sextus Julius were consuls, there appeared a very strange prodigy of the earth (as I have read in the books of Ætruscan discipline), which happened in the province of Mutina. Two mountains shocked against each other, approaching and retiring with the most dreadful noise. They, at the same time, and in the midst of the day, appeared to cast forth fire and smoke, while a vast number of Roman knights and travellers from the Æmilian Way stood and continued amazed spectators. Several towns were destroyed by this shock; and all the animals that were near them were killed." In the time of Trajan, the city of Antioch and a great part of the adjacent country was buried by an earthquake. About three hundred years

after, in the times of Justinian, it was once more destroyed, together with forty thousand inhabitants: and, after an interval of sixty years, the same ill-fated city was a third time overturned, with the loss of not less than sixty thousand souls. In the year 1182, most of the cities of Syria, and the kingdom of Jerusalem, were destroyed by the same accident. In the year 1594, the Italian historians describe an earthquake at Puteoli, which caused the sea to retire two hundred yards from its former bed.

But one of those more particularly described in history is that of the year 1693, the damages of which were chiefly felt in Sicily, but its motion perceived in France, Germany, and England. It extended to a circumference of 2,600 leagues—chiefly affecting the sea-coasts and great rivers, more perceivable also upon the mountains than in the valleys. Its motions were so rapid, that those who lay at their length were tossed from side to side, as upon a rolling billow. The walls were dashed from their foundations; and no less than fifty-four cities, with an incredible number of villages, were either destroyed or greatly damaged. The city of Catania, in particular, was utterly overthrown. A traveller, who was on his way thither, at the distance of some miles perceived a black cloud, like night, hanging over the place. The sea suddenly began to roar, and *Ætna* to send forth great spires of flame; soon after a shock ensued, with a noise as if all the artillery in the world had been at once discharged. Our traveller, being obliged to alight instantly, felt himself raised a foot from the ground; and, turning his eyes to the city, he with amazement saw nothing but a thick cloud of dust in the air. The birds flew about astonished—the sun was darkened—the beasts ran howling from the hills; and, although the shock did not continue above three minutes, yet nearly 19,000 of the inhabitants of Sicily perished in the ruins. Catania, to which the describer was travelling, seemed the principal scene of ruin; its site only was to be found, and not a footprint of its former magnificence was to be seen remaining.

The earthquake which happened in Jamaica in 1692 was very terrible, and its description sufficiently minute. "In two minutes time it destroyed the town of Port-Royal, and sunk the houses in a gulf forty fathoms deep. It was attended with a hollow rumbling noise like that of thunder, and in less than a minute three-parts of the houses and their inhabitants were all quite sunk under water. While they were thus swallowed up on one side of the street, on the other the houses were thrown into heaps—the sand of the street rising like the waves of the sea, lifting up those that stood upon it, and immediately overwhelming them in pits. All the wells discharged their waters with the most vehement agitation. The sea felt an equal share of turbulence, and, bursting over its mounds, deluged all that came in its way. The fissures of the earth were in some places so great, that one of the streets appeared twice as broad as formerly. In many places, however, it opened and closed again, continuing this agitation for some time. Of these openings, two or three hundred might be seen at a time; in some whereof the people were swallowed up—in others, the earth closing caught them by the middle, and thus instantly crushed them to death. Other openings, still more dreadful than the rest, swallowed up whole streets; and others, more formidable still, spouted up whole cataracts of water, drowning such as the earthquake had spared. The whole was attended with the most noisome stench; while the thundering of the distant falling mountains, the whole sky overcast with a dusky gloom, and the crash of falling habitations, gave unspeakable horror to the scene. After this dreadful calamity was over, the whole island seemed converted into a scene of desolation; scarce a planter's house was left standing—almost all were swallowed up; houses, people, trees, shared one universal ruin, and in their places appeared great pools

of water, which, when dried up by the sun, left only a plain of barren sand, without any vestige of former inhabitants. Most of the rivers during the earthquake were stopped by the falling in of the mountains; and it was not till after some time that they made themselves new channels. The mountains seemed particularly attacked by the force of the shock; and it was supposed that the principal seat of the concussion was among them. Those who were saved got on board ships in the harbour, where many remained above two months—the shocks continuing during that interval with more or less violence every day."

As this description seems to exhibit all the appearances that usually make up the catalogue of terrors belonging to an earthquake, I will suppress the detail of that which happened at Lisbon in our times, and which is too recent to require a description. In fact, there are few particulars in the accounts of those who were present at that scene of desolation that we have not more minutely and accurately transmitted to us by former writers, whose narratives I have for that reason preferred. I will therefore close this description of human calamities with the account of the dreadful earthquake at Calabria, in 1638. It is related by the celebrated Kircher, as it happened while he was on his journey to visit Mount *Ætna*, and the rest of the wonders that lie towards the south of Italy. I need scarce inform the reader that Kircher is considered by scholars as one of the greatest prodigies of learning.

"Having hired a boat, in company with four more, we launched, on the 24th of March, from the harbour of Messina, in Sicily, and arrived the same day at the promontory of Pelorus. Our destination was for the city of Euphæmia, in Calabria, where we had some business to transact, and where we designed to tarry some time. However, Providence seemed willing to cross our designs, for we were obliged to continue for three days at Pelorus, on account of the weather; and though we often put out to sea, yet we were as often driven back. At length, however, wearied with the delay, we resolved to prosecute our voyage; and, although the sea seemed more than usually agitated, yet we ventured forward. The gulf of Charybdis, which we approached, seemed whirled round in such a manner as to form a vast hollow, verging to a point in the centre. Proceeding onward, and turning my eyes to *Ætna*, I saw it cast forth large volumes of smoke, of mountainous size, which entirely covered the whole island, and blotted out the very shores from my view. This, together with the dreadful noise and the sulphureous stench, which was strongly perceived, filled me with apprehensions that some more dreadful calamity was impending. The sea itself seemed to wear a very unusual appearance; those who have seen a lake in a violent shower of rain covered all over with bubbles, will conceive some idea of its agitation. My surprise was still increased by the calmness and serenity of the weather; not a breeze, not a cloud which might be supposed to put all Nature thus into motion. I therefore warned my companions that an earthquake was approaching; and after some time, making for the shore with all possible diligence, we landed at Tropæa, happy and thankful for having escaped the threatening dangers of the sea.

"But our triumph on land was of short duration; for we had scarce arrived at the Jesuits' College in that city, when our ears were stunned with a horrid sound resembling that of an infinite number of chariots driven fiercely forward, the wheels rattling and the thongs cracking. Soon after this a most dreadful earthquake ensued, so that the whole tract upon which we stood seemed to vibrate, as if we were in the scale of a balance that continued wavering. This motion, however, soon grew more violent; and, being no longer able to keep my legs, I was thrown prostrate upon the ground. In the meantime, the universal ruin round me redoubled my

amazement. The crash of falling houses, the tottering of towers, and the groans of the dying, all contributed to raise my terror and despair. On every side of me I saw nothing but a scene of ruin, and danger threatening wherever I should fly. I commended myself to God, as my last refuge. At that hour, O how vain was every sublunary happiness!—wealth, honour, empire, wisdom, all mere useless sounds, and as empty as the bubbles in the deep. Just standing on the threshold of eternity, nothing but God was my pleasure; and the nearer I approached I only loved Him the more. After some time, however, finding that I remained unhurt amidst the general concussion, I resolved to venture for safety, and, running as fast as I could, reached the shore, but almost terrified out of my reason. I did not search long here till I found the boat in which I had landed, and my companions also, whose terrors were even greater than mine. Our meeting was not of that kind where every one is desirous of telling his own happy escape: it was all silence, and a gloomy dread of impending terrors.

"Leaving this seat of desolation, we prosecuted our voyage along the coast, and the next day arrived at Rochetta, where we landed, although the earth still continued in violent agitations. But we were scarce arrived at our inn when we were once more obliged to return to the boat, and in about half an hour we saw the greatest part of the town, and the inn at which we had put up, dashed to the ground—burying all its inhabitants beneath its ruins.

"In this manner, proceeding onward in our little vessel, finding no safety on land, and yet, from the smallness of our boat, having but a very dangerous continuance at sea, we at length landed at Lopizium, a castle midway between Tropæa and Euphæmia, the city to which, as I said before, we were bound. Here, wherever I turned my eyes, nothing but scenes of ruin and horror appeared; towns and castles levelled to the ground; Strombalo, though at sixty miles distance, belching forth flames in an unusual manner, and with a noise which I could distinctly hear. But my attention was quickly turned from more remote to contiguous danger. The rumbling found of an approaching earthquake, which we by this time were grown acquainted with, alarmed us for the consequences; it every moment seemed to grow louder, and to approach more near. The place on which we stood now began to shake most dreadfully, so that, being unable to stand, my companions and I caught hold of whatever shrub grew next us, and supported ourselves in that manner.

"After some time, this violent paroxysm ceasing, we again stood up, in order to prosecute our voyage to Euphæmia, which lay within sight. In the meantime, while we were preparing for this purpose, I turned my eyes towards the city, but could see only a frightful dark cloud, that seemed to rest upon the place. This the more surprised us, as the weather was so very serene. We waited, therefore, till the cloud was dispersed; then turning to look for the city, it was totally sunk. Wonderful to tell! nothing but a dismal and putrid lake was seen where it stood. We looked about to find some one that could tell us of its sad catastrophe, but could see none! All was become a melancholy solitude—a scene of hideous desolation. Thus proceeding pensively along, in quest of some human being that could give us some little information, we at length saw a boy sitting by the shore, and seemingly stupified with terror. Of him, therefore, we inquired concerning the fate of the city, but he could not be induced to give us an answer. We intreated him with every expression of tenderness and pity to tell us; but his senses were quite wrapt up in contemplation of the danger he had escaped. We offered him some victuals, but he seemed to loathe the sight. We still persisted in our offices of kindness; but he only pointed to the place of the city, like one out

of his senses; and then, running up into the woods, was never heard of after. Such was the fate of the city of Euphæmia! and as we continued our melancholy course along the shore, the whole coast, for the space of two hundred miles, presented nothing but the remains of cities, and men scattered without a habitation over the fields. Proceeding thus along, we at length ended our distressful voyage by arriving at Naples, after having escaped a thousand dangers both at sea and land."

The reader, I hope, will excuse me for this long translation from a favourite writer, and that the sooner, as it contains some particulars relative to earthquakes not to be found elsewhere. From the whole of these accounts, we may gather that the most concomitant circumstances are these:

A rumbling sound before the earthquake. This proceeds from the air or fire, or both, forcing their way through the chasms of the earth, and endeavouring to get free, which is also heard in volcanoes.

A violent agitation or heaving of the sea, sometimes before and sometimes after that on land. This agitation is only a similar effect produced on the waters with that on land, and may be called, for the sake of perspicuity, a "seaquake;" and this, also, is produced by volcanoes.

A spouting of waters to great heights. It is not easy to describe the manner in which this is performed; but volcanoes also perform the same—Vesuvius being known frequently to eject a vast body of water.

A rocking of the earth to and fro, and sometimes a perpendicular bouncing, if it may be so called, of the same. This difference chiefly arises from the situation of the place with respect to the subterranean fire. Directly under, it lifts; at a farther distance, it rocks.

Some earthquakes seem to travel onward, and are felt in different countries at different hours of the same day. This arises from the great shock being given to the earth at one place, and which, being communicated onward by an undulatory motion, successively affects different regions in its progress—as the blow given by a stone falling in a lake, is not perceived on the shore till some time after the first concussion.

The shock is sometimes instantaneous, like the explosion of gunpowder; and sometimes tremulous, and continuing for several minutes. The nearer the place where the shock is first given, the more instantaneous and simple it appears. At a greater distance, the earth redoubles the first blow with a sort of vibratory continuation.

As waters have generally so great a share in producing earthquakes, it is not to be wondered that they should generally follow those breaches made by the force of fire, and appear in the great chasms which the earthquake has opened.

These are some of the most remarkable phenomena of earthquakes, presenting a frightful assemblage of the most terrible effects of air, earth, fire, and water.

The valley of Solfatara, near Naples, seems to exhibit, in a minuter degree, whatever is seen of this horrible kind on the great theatre of Nature. This plain, which is about twelve hundred feet long, and a thousand broad, is embosomed in mountains, and has in the middle of it a lake of noisome blackish water, covered with a bitumen that floats upon its surface. In every part of this plain, caverns appear smoking with sulphur, and often emitting flames. The earth, wherever we walk over it, trembles beneath the feet. Noises of flames and the hissing of waters are heard at the bottom. The water sometimes spouts up eight or ten feet high. The most noisome fumes, foetid water, and sulphureous vapours, offend the smell. A stone thrown into any of the caverns is ejected again with considerable violence. These appearances generally prevail when the sea is any way disturbed; and the whole seems to exhibit the appearance of an earthquake in miniature. However, in this smaller scene of wonders, as well as in the greater,

there are many appearances for which, perhaps, we shall never account; and many questions may be asked which no conjectures can thoroughly resolve. It was the fault of the philosophers of the last age to be more inquisitive after the causes of things than after the things themselves. They seemed to think that a confession of ignorance cancelled their claims to wisdom. But the present age has grown, if not more inquisitive, at least more modest; and none are now ashamed of that ignorance which labour can neither remedy nor remove.

## CHAP. XI.

### OF THE APPEARANCE OF NEW ISLANDS AND TRACTS, AND OF THE DISAPPEARING OF OTHERS.

Hitherto we have taken a survey only of the evils which are produced by subterranean fires, but we have mentioned nothing of the benefits they may possibly produce. They may be of use in warming and cherishing the ground, in promoting vegetation, and giving a more exquisite flavour to the productions of the earth. The imagination of a person who has never been out of our own mild region, can scarcely reach to that luxuriant beauty with which all Nature appears clothed in those very countries that we have just now described as desolated by earthquakes, and undermined by subterranean fires. It must be granted, therefore, that though in those regions they have a greater share in the dangers, they have also a larger proportion in the benefits of Nature.

But there is another advantage arising from subterranean fires which, though hitherto disregarded by man, yet may one day become serviceable to him; I mean, that while they are found to swallow up cities and plains in one place, they are also known to form promontories and islands in another. We have many instances of islands being thus formed in the midst of the sea, which, though for a long time barren, have afterwards become fruitful seats of happiness and industry.

New islands are formed in two ways—either suddenly, by the action of subterranean fires, or more slowly, by the deposition of mud carried down by rivers, and stopt by some accident. With respect particularly to the first, ancient historians and modern travellers give us such accounts as we can have no room to doubt of. Seneca assures us, that in his time the island of Therasia appeared unexpectedly to some mariners, as they were employed in another pursuit. Pliny states that thirteen islands in the Mediterranean appeared at once emerging from the water—the cause of which he ascribes rather to the retiring of the sea in those parts than to any subterranean elevation. However, he mentions the island of Hiera, near that of Therasia, as formed by subterranean explosions; and adds to his list several others, formed in the same manner, in one of which he relates that fish were found in great abundance, and that all those who eat of them died shortly after.

"On the twenty-fourth of May, in the year 1707, a slight earthquake was perceived at Santorin; and the day following, at sun-rising, an object was seen by the inhabitants of that island, at two or three miles distance at sea, which appeared like a floating rock. Some persons, desirous either of gain or incited by curiosity, went there, and found, even while they stood upon this rock, that it seemed to rise beneath their feet. They perceived, also, that its surface was covered with pumice-stones and oysters, which it had raised from the bottom. Every day after, until the fourteenth of June, this rock seemed considerably to increase; and then was found to be half a mile round, and thirty feet above the sea. The earth of which it was composed seemed whitish, with a small proportion of clay. Soon after this the

sea again appeared troubled, and steams arose which were very offensive to the inhabitants of Santorin. But on the sixteenth of the succeeding month, seventeen or eighteen rocks more were seen to rise out of the sea, and at length to join together. All this was accompanied with the most terrible noise, and fires that proceeded from the island that was newly formed. The whole mass, however, of all this new-formed earth, uniting, increased every day, both in height and breadth, and, by the force of its explosions, cast forth rocks to seven miles distance. This continued to bear the same dreadful appearances till the month of November in the same year; and it is at present a volcano which sometimes renews its explosions. It is about three miles in circumference, and more than from thirty-five to forty feet high."

A new island was found, in the year 1720, near that of Tercera, near the continent of Africa, by the same causes. In the beginning of December, at night, there was a terrible earthquake at that place, and the top of a new island appeared, which cast forth smoke in vast quantities. The pilot of a ship, who approached it, sounded on one side of this island, and could not find ground at sixty fathoms. At the other side the sea was totally tinged of a different colour, exhibiting a mixture of white, blue, and green, and was very shallow. This island, on its first appearance, was larger than it is at present—for it has, since that time, sunk in such a manner as to be scarce above water.

A traveller, whom these appearances could not avoid affecting, speaks of them in this manner:—"What can be more surprising than to see fire not only break out of the bowels of the earth, but also make itself a passage through the waters of the sea! What can be more extraordinary or foreign to our common notion of things, than to see the bottom of the sea rise up into a mountain above the water, and become so firm an island as to be able to resist the violence of the greatest storms! I know that subterranean fires, when pent in a narrow passage, are able to raise up a mass of earth as large as an island; but that this should be done in so regular and exact a manner, that the water of the sea should not be able to penetrate and extinguish those fires—that after having made so many passages they should retain force enough to raise the earth—and, in fine, after having been extinguished, that the mass of earth should not fall down, or sink again with its own weight, but still remain in a manner suspended over the great arch below!—this is what to me seems more surprising than anything that has been related of Mount *Ætna*, *Vesuvius*, or any other volcano."

Such are his sentiments; however, there are few of these appearances any way more extraordinary than those attending volcanoes and earthquakes in general. We are not more to be surprised that inflammable substances should be found beneath the bottom of the sea, than at similar depths on land. These have all the force of fire giving expansion to air, and tending to raise the earth at the bottom of the sea, till it at length heaves above water. These marine volcanoes are not so frequent; for, if we may judge of the usual procedure of Nature, it must very often happen, before the bottom of the sea is elevated above the surface, a chasm is opened in it, and then the water pressing in, extinguishes the volcano before it has time to produce its effects. This extinction, however, is not effected without very great resistance from the fire beneath. The water, upon dashing into the cavern, is very probably at first ejected back with great violence; and thus some of those amazing water-spouts are seen, which have so often astonished the mariner and excited curiosity. But of these in their place.

Besides the production of those islands by the action of fire, there are others, as was said, produced by rivers or seas carrying mud, earth, and such like substances,

along with their currents; and at last depositing them in some particular place. At the mouths of most great rivers, there are to be seen banks thus formed by the sand and mud carried down with the stream, which have rested at that place, where the force of the current is diminished by its junction with the sea. These banks by slow degrees increase at the bottom of the deep; the water in those places is at first found by mariners to grow more shallow; the bank soon heaves up above the surface; it is considered, for a while, as a tract of useless and barren sand; but the seeds of some of the more hardy vegetables are driven thither by the wind, take root, and, thus binding the sandy surface, the whole spot is clothed in time with a beautiful verdure. In this manner there are delightful and inhabited islands at the mouths of many rivers, particularly the Nile, the Po, the Mississippi, the Ganges, and the Senegal. There has been, in the memory of man, a beautiful and large island formed in this manner at the mouth of the river Nanquin, in China, made from depositions of mud at its opening: it is not less than sixty miles long, and about twenty broad. La Loubere informs us, in his voyage to Siam, that these sand-banks increase every day at the mouths of all the great rivers in Asia; and hence, he asserts, that the navigation up these rivers becomes every day more difficult, and will, at one time or other, be totally obstructed. The same may be remarked with regard to the Wolga, which has at present 70 openings into the Caspian Sea; and of the Danube, which has seven into the Euxine. We have had an instance of the formation of a new island not very long since at the mouth of the Humber, in England. "It began its appearance at low water, for the space of a few hours; and was buried again till the next tide's retreat. Thus, successively, it lived and died until the year 1666, when it began to maintain its ground against the insult of the waves, and first invited the aid of human industry. A bank was thrown about its rising grounds; and, being thus defended from the incursions of the sea, it became firm and solid, and, in a short time, afforded good pasturage for cattle. It is about nine miles in circumference, and is worth to the proprietor about eight hundred pounds a-year." It would be endless to mention all the islands that have been thus formed, and the advantages that have been derived from them. However, it is frequently found, that new islands may be often considered as only turning the rivers from their former beds; so that, in proportion as land is gained at one part, it is lost by the overflowing of some other.

Little, therefore, is gained by such accessions; nor is there much more by the new islands which are sometimes formed from the spoils of the continent. Mariners assure us that there are sometimes whole plains unrooted from the main lands by floods and tempests. These being carried out to sea, with all the trees and animals upon them, are frequently seen floating in the ocean, and exhibiting a surprising appearance of rural tranquillity in the midst of danger. The greatest part, however, having the earth at their roots at length washed away, are dispersed, and their animals drowned; but now and then some are found to brave the fury of the ocean, till, being stuck either among rocks or sands, they again take firm footing, and become permanent islands.

As different causes have thus concurred to produce new islands, so we have accounts of others that the same causes have contributed to destroy. We have already seen the power of earthquakes exerted in sinking whole cities, and leaving lakes in their room. There have been islands, and regions also, that have shared the same fate, and have sunk with their inhabitants ever more to be heard of. Thus Pausanias tells us of an island, called Chrysee, that was sunk near Lemnos. Pliny mentions several; among others, the island Cea, for thirty miles, having been washed away, with several

thousands of its inhabitants. But of all the noted devastations of this kind, the total submersion of the island of Atalantis, as mentioned by Plato, has been most the subject of speculation. Mankind in general now consider the whole of his description as an ingenious fable; but when fables are grown famous by time and authority, they become an agreeable, if not a necessary, part of literary information.

"About nine thousand years are passed," says Plato, "since the island of Atalantis was in being. The priests of Egypt were well acquainted with it; and the first heroes of Athens gained much glory in their wars with the inhabitants. This island was as large as Asia Minor and Syria united, and was situated beyond the Pillars of Hercules, in the Atlantic Ocean. The beauty of the buildings and the fertility of the soil were far beyond anything a modern imagination can conceive; gold and ivory were everywhere common; and fruits of the earth offered themselves without cultivation. The arts and courage of the inhabitants were not inferior to the happiness of their situation; and they were frequently known to make conquests, and overrun the continents of Europe and Asia." The imagination of the poetical philosopher riots in the description of the natural and acquired advantages which they long enjoyed in this charming region. "If," says he, "we compare that country to our own, ours will appear a mere wasted skeleton when opposed to it. The mountains to the very tops were clothed with fertility, and poured down rivers to enrich the plains below."

However, all these beauties and benefits were destroyed in one day by an earthquake sinking the earth, and the sea overwhelming it. At present, not the smallest vestige of such an island is to be found: Plato remains as the only authority for its existence; and philosophers dispute about its situation. It is not for me to enter into the controversy, when there appears but little probability to support the fact; and, indeed, it would be useless to run back nine thousand years in search of difficulties, as we are surrounded with objects that more closely affect us, and which demand admiration at our very doors. When I consider, as Lactantius suggests, the various vicissitudes of Nature—lands swallowed by yawning earthquakes, or overwhelmed in the deep; rivers and lakes disappearing, or dried away; mountains levelled into plains, and plains swelling up into mountains—I cannot help regarding this earth as a place of very little stability—as a transient abode of still more transitory beings.

## CHAP. XII.

### OF MOUNTAINS

Having at last, in some measure, emerged from the depths of the earth, we come to a scene of greater splendour—the contemplation of its external appearance. In this survey, its mountains are the first objects that strike the imagination and excite our curiosity. There is not, perhaps, anything in all Nature that impresses an unaccustomed spectator with such ideas of awful solemnity as these immense piles of Nature's erecting, that seem to mock the minuteness of human magnificence.

In countries where there are nothing but plains, the smallest elevations are apt to excite wonder. In Holland, which is all a flat, they show a little ridge of hills near the sea-side, which Boerhaave generally marked out to his pupils as being mountains of no small consideration. What would be the sensations of such an auditory, could they at once be presented with a view of the heights and precipices of the Alps or the Andes! Even among us in England, we have no adequate idea

of a mountain-prospect; our hills are generally sloping from the plain, and clothed to the very top with verdure; we can scarce, therefore, lift our imaginations to those immense piles, whose tops peep up behind intervening clouds, sharp and precipitate, and reach to heights that human avarice or curiosity have never been able to ascend.

We in this part of the world are not, for that reason, so immediately in the question which has so long been agitated among philosophers, concerning what gave rise to these inequalities on the surface of the globe. In our own happy region we generally see no inequalities but such as contribute to use and beauty; and we therefore are amazed at a question inquiring how such necessary inequalities came to be formed, and seeming to express a wonder how the globe comes to be so beautiful as we find it. But though with us there may be no great cause for such a demand, yet in those places where mountains deform the face of Nature—where they pour down cataracts, or give fury to tempests—there seems to be good reason for inquiry either into their causes or their uses. It has therefore been asked by many in what manner mountains have come to be formed, or for what uses they are designed.

To satisfy curiosity in these respects much reasoning has been employed, and very little knowledge propagated. With regard to the first part of the demand—the manner in which mountains were formed—we have already seen the conjectures of different philosophers on that head—one supposing that they were formed from the earth's broken shell at the time of the deluge; another, that they existed from the creation, and acquired their deformities in process of time; a third, that they owed their origin to earthquakes; and still a fourth, with much more plausibility than the rest, ascribing them entirely to the fluctuations of the deep, which he supposes in the beginning to have covered the whole earth. Such as are pleased with disquisitions of this kind may consult Burnet, Whiston, Woodward, or Buffon. Nor would I be thought to decry any mental amusements, that at worst keep us innocently employed; but, for my own part, I cannot help wondering how the opposite demand has never come to be made, and why philosophers have never asked how we come to have plains. Plains are sometimes more prejudicial to man than mountains. Upon plains an inundation has a greater power; the beams of the sun are often collected there with suffocating fierceness; they are sometimes found desert for several hundred miles together, as in the country east of the Caspian Sea, although otherwise fruitful, merely because there are no risings nor depressions to form reservoirs, or collect the smallest rivulet of water. The most rational answer, therefore, why either mountains or plains were formed, seems to be that they were thus fashioned by the hand of Wisdom, in order that pain and pleasure should be so contiguous as that mortality might be exercised either in bearing the one or communicating the other.

Indeed, the more I consider this dispute respecting the formation of mountains, the more I am struck with the futility of the question. There is neither a straight line nor an exact superficies in all Nature. If we consider a circle, even with mathematical precision, we shall find it formed of a number of small right lines joining at angles together. These angles, therefore, may be considered in a circle as mountains are upon our globe; and to demand the reason for the one being mountainous or the other angular, is only to ask why a circle is a circle, or a globe is a globe. In short, if there be no surface without inequality in Nature, why should we be surprised that the earth has such? It has often been said that the inequalities of its surface are scarcely distinguishable, if compared with its magnitude; and I think we have every reason to be content with the answer.

Some, however, have avoided the difficulty by urging the final cause. They allege that mountains have been formed merely because they are useful to man. This carries the inquirer but a part of the way; for no one can affirm that in all places they are useful. The contrary is known, by horrid experience, in those valleys that are subject to their influence. However, as the utility of any part of our earthly habitation is a very pleasing and flattering speculation to every philosopher, it is not to be wondered that much has been said to prove the usefulness of these. For this purpose, many conjectures have been made that have received a degree of assent even beyond their evidence; for men were unwilling to become more miserably wise.

It has been alleged, as one principal advantage that we derive from them, that they serve, like hoops or ribs, to strengthen our earth, and to bind it together. In consequence of this theory, Kircher has given us a map of the earth, in this manner hooped with its mountains; which might have a more solid foundation, did it entirely correspond with truth.

Others have found a different use for them, especially when they run surrounding our globe; which is, that they stop the vapours which are continually travelling from the equator to the poles; for these being urged by the heat of the sun from the warm regions of the line, must all be accumulated at the poles if they were not stopped in their way by those high ridges of mountains which cross their direction. But an answer to this may be, that all the great mountains in America lie lengthwise, and therefore do not cross their direction.

But to leave these remote advantages, others assert that not only the animal but vegetable part of the creation would perish for want of convenient humidity, were it not for their friendly assistance. Their summits are, by these, supposed to arrest, as it were, the vapours which float in the regions of the air. Their large inflexions and channels are considered as so many basins prepared for the reception of those thick vapours and impetuous rains which descend into them. The huge caverns beneath are so many magazines or conservatories of water for the peculiar service of man; and those orifices by which the water is discharged upon the plain are so situated as to enrich and render them fruitful, instead of returning through subterraneous channels to the sea, after the performance of a tedious and fruitless circulation.

However this be, certain it is that almost all our great rivers find their source among mountains; and, in general, the more extensive the mountain the greater the river: thus the river Amazon, the greatest in the world, has its source among the Andes, which are the highest mountains on the globe; the river Niger travels a long course of several hundred miles from the Mountains of the Moon, the highest in all Africa; and the Danube and the Rhine proceed from the Alps, which are probably the highest mountains of Europe.

It need scarcely be said that, with respect to height, there are many sizes of mountains, from the gently rising upland to the tall, craggy precipice. The appearance is different in different magnitudes. The first are clothed with verdure to the very tops, and only seem to ascend to improve our prospects, or supply us with a purer air: but the lofty mountains of the other class have a very different aspect. At a distance their tops are seen, in wavy ridges, of the very colour of the clouds, and only to be distinguished from them by their figure, which, as I have said, resemble the billows of the sea. As we approach, the mountain assumes a deeper colour; it gathers upon the sky, and seems to hide half the horizon behind it. Its summits also are become more distinct, and appear with a broken and perpendicular line. What at first seemed a single hill is now found to be a chain of continued mountains, whose tops, running along in ridges, are embosomed in each other; so

that the curvatures of one are fitted to the prominences of the opposite side, and form a winding valley between, often of several miles in extent; and all the way continuing nearly of the same breadth.

Nothing can be finer or more exact than Mr. Pope's description of a traveller straining up the Alps. Every mountain he comes to he thinks will be the last; he finds, however, an unexpected hill rise before him; and that being scaled, he finds the highest summit almost at as great a distance as before. Upon quitting the plain, he might have left a green and a fertile soil, and a climate warm and pleasing. As he ascends, the ground assumes a more russet colour; the grass becomes more mossy, and the weather more moderate. Still, as he ascends, the weather becomes more cold and the earth more barren. In this dreary passage he is often entertained with a little valley of surprising verdure, caused by the reflected heat of the sun collected into a narrow spot on the surrounding heights. But it much more frequently happens that he sees only frightful precipices beneath, and lakes of amazing depths from whence rivers are formed, and fountains derive their origin. On those places next the highest summits vegetation is scarcely carried on; here and there a few plants of the most hardy kind appear. The air is tolerably cold—either continually refrigerated with frosts or disturbed with tempests. All the ground here wears an eternal covering of ice, and snows that seem constantly accumulating. Upon emerging from this war of the elements, he ascends into a purer and senerer region, where vegetation is entirely ceased; where the precipices, composed entirely of rocks, rise perpendicular above him; while he views beneath him all the combat of the elements—clouds at his feet, and thunders darting upward from their bosoms below. A thousand meteors, which are never seen on the plain, present themselves. Circular rainbows, mock suns, the shadow of the mountain projected upon the body of the air; and the traveller's own image, reflected as in a looking-glass, upon the opposite cloud.

Such are, in general, the wonders that present themselves to a traveller in his journey either over the Alps or the Andes. But we must not suppose that this picture exhibits either a constant or an invariable likeness of those stupendous heights. Indeed, nothing can be more capricious or irregular than the forms of many of them. The tops of some run in ridges for a considerable length without interruption; in others, the line seems indented by great valleys to an amazing depth. Sometimes a solitary and single mountain rises from the bosom of the plain; and sometimes extensive plains, and even provinces, as those of Savoy and Quito, are found embosomed near the tops of mountains. In general, however, those countries that are most mountainous are the most barren and uninhabitable.

If we compare the heights of mountains with each other, we shall find that the greatest and highest are found under the line. It is thought by some that the rapidity of the earth's motion in these parts, together with the greatness of the tides there, may have thrown up those stupendous masses of earth. But, be the cause as it may, it is a remarkable fact, that the inequalities of the earth's surface are greatest there. Near the poles, the earth, indeed, is craggy and uneven enough; but the height of the mountains there is very inconsiderable. On the contrary, at the equator, where Nature seems to sport in the amazing size of all her productions, the plains are extensive, and the mountains remarkably lofty. Some of them are known to rise three miles perpendicular above the bed of the ocean.

To enumerate the most remarkable of these, according to their size, we shall begin with the Andes, of which we have an excellent description by Ulloa, who went thither by command of the King of Spain, in company with the French Academicians, to measure a degree of

the meridian. His journey up these mountains is too curious not to give an extract from it.

After many incommodious days' sailing up the river Guayquil, he arrived at Caracol, a town situated at the foot of the Andes. Nothing could exceed the inconveniences which he experienced in this voyage, from the flies and mosquitoes (an animal resembling our gnat). "We were the whole day," says he, "in continual motion to keep them off; but at night our torments were excessive. Our gloves, indeed, were some defence to our hands, but our faces were entirely exposed; nor were our clothes a sufficient defence for the rest of our bodies—for their stings, penetrating through the cloth, caused a very painful and fiery itching. One night, in coming to an anchor near a large handsome house that was uninhabited, we had no sooner seated ourselves in it than we were attacked on all sides by swarms of mosquitoes, so that it was impossible to have one moment's quiet. Those who had covered themselves with clothes, made for this purpose, found not the smallest defence; wherefore, hoping to find some relief in the open fields, they ventured out, though in danger of suffering in a more terrible manner from the serpents. But both places were equally obnoxious. On quitting this inhospitable retreat, we the next night took up our quarters in a house that was inhabited; the host of which, being informed of the terrible manner we had past the night before, he gravely told us that the house we so greatly complained of had been forsaken on account of its being the purgatory of a soul. But we had more reason to believe that it was quitted on account of its being the purgatory of the body. After having journeyed for upwards of three days through boggy roads, in which the mules at every step sunk up to their bellies, we began at length to perceive an alteration in the climate; and having been long accustomed to heat, we now began to feel it grow sensibly colder.

"If is remarkable, that at Tariguagua we often see instances of the effects of two opposite temperatures in two persons happening to meet—one of them leaving the plains below, and the other descending from the mountain. The former thinks the cold so severe, that he wraps himself up in all the garments he can secure; while the latter finds the heat so great, that he is scarce able to bear any clothes whatsoever. The one thinks the water so cold that he avoids being sprinkled by it; the other is so delighted with its warmth that he uses it as a bath. Nor is the case very different in the same person, who experiences the same diversity of sensation upon his journey up and upon his return. This difference only proceeds from the change naturally felt on leaving a climate to which one has been accustomed, and coming into another of an opposite temperature.

"The ruggedness of the road from Tariguagua leading up the mountain is not easily described. In some parts the declivity is so great, that the mules can scarce keep their footing; and in others, the acclivity is equally difficult. The trouble of having people going before to mend the road, the pains arising from the many falls and bruises, and the being constantly wet to the skin, might be supported, were not these inconveniences augmented by the sight of such frightful precipices and deep abysses as must fill the mind with ceaseless terror. There are some places where the road is so steep, and yet so narrow, that the mules are obliged to slide down, without making any use of their feet whatsoever. On one side of the rider, in this situation, rises an eminence of several hundred yards; and on the other, an abyss of equal depth; so that if he in the least checks his mule, so as to destroy the equilibrium, they both must unavoidably perish.

"After having travelled about nine days in this manner, slowly winding along the side of the mountain, we began to find the whole country covered with a hoar frost; and a hut in which we lay had ice on it. Hav-

ing escaped many perils, we at length, after a journey of fifteen days, arrived upon the plain, on the extremity of which stands the city of Quito, the capital of one of the most charming regions upon earth. Here, in the centre of the torrid zone, the heat is not only very tolerable, but in some places the cold also is painful. Here they enjoy all the temperature and advantages of perpetual spring—their fields being always covered with verdure, and enamelled with flowers of the most lively colours. However, although this beautiful region be higher than any other country in the world, and although it took up so many days of painful journey in the ascent, it is still overlooked by tremendous mountains—their sides covered with snow, and yet flaming with volcanoes at the top. These seemed piled one upon the other, and rise to a most astonishing height, with great coldness. However, at a determined point above the surface of the sea, the congelation is found at the same height in all the mountains. Those parts which are not subject to a continual frost have here and there growing upon them a rush, resembling the genista, but much more soft and flexible. Towards the extremity of the part where the rush grows, and the cold begins to increase, is found a vegetable, with a round, bulbous head, which, when dried, becomes of amazing elasticity. Higher up, the earth is entirely bare of vegetation, and seems covered with eternal snow. The most remarkable mountains are, that of Cotopaxi (already described as a volcano), Chimborazo, and Pichincha. Cotopaxi is more than three geographical miles above the surface of the sea: the rest are much inferior. On the top of the latter was my station for measuring a degree of the meridian, where I suffered particular hardships from the intenseness of the cold and the violence of the storms. The sky around was, in general, involved in thick fogs, which, when they cleared away, and the clouds, by their gravity, moved nearer to the surface of the earth, they appeared surrounding the foot of the mountain, at a vast distance below, like a sea encompassing an island in the midst of it. When this happened, the horrid noises of tempests were heard from beneath, then discharging themselves on Quito and the neighbouring country. I saw the lightnings issue from the clouds, and heard the thunders roll far beneath me. All this time, while the tempest was raging below, the mountain top where I was placed enjoyed a delightful serenity; the wind was abated, the sky clear, and the enlivening rays of the sun moderated the severity of the cold. However, this was of no very long duration, for the wind returned with all its violence, and with such velocity as to dazzle the sight; whilst my fears were increased by the dreadful concussions of the precipice and the fall of enormous rocks—the only sounds that were heard in this frightful situation."

Such is the animated picture of these mountains, as given us by this ingenious Spaniard; and I believe the reader will wish that I had made the quotation still longer. A passage over the Alps, or a journey across the Pyrenees, appear petty trips or excursions in the comparison; and yet these are the most lofty mountains we know of in Europe.

If we compare the Alps with the mountains already described, we shall find them but little more than one half of the height of the former. The Andes, upon being measured by the barometer, are found above three thousand one hundred and thirty-six fathoms above the surface of the sea; whereas the highest point of the Alps is not above sixteen hundred. The one, in other words, is above three miles high; the other about a mile and a half. The highest mountains in Asia are Mount Taurus, Mount Immaus, Mount Caucasus, and the mountains of Japan. Of these, none equals the Andes in height—although Mount Caucasus, which is the highest of them, makes very near approaches. In Africa, the Mountains of the Moon—famous for giving source

to the Niger and the Nile—are rather more noted than known. Of the Peak of Teneriffe, one of the Canary Islands that lie off this coast, we have more certain information. In the year 1727 it was visited by a company of English merchants, who travelled up to the top, where they observed its height, and the volcano on its very summit. They found it a heap of mountains, the highest of which rises over the rest like a sugar-loaf, and gives a name to the whole mass. It is computed to be a mile and a half perpendicular from the surface of the sea. Kircher gives us an estimate of the heights of most of the other great mountains in the world; but as he has taken his calculations in general from the ancients, or from modern travellers who had not the art of measuring them, they are quite incredible. The art of taking the heights of places by the barometer is an ingenious invention. As the air grows lighter as we ascend, the fluid in the tube rises in due proportion: thus the instrument, being properly marked, gives the height with a tolerable degree of exactness—at least, enough to satisfy curiosity.

Few of our great mountains have been estimated in this manner—travellers having, perhaps, been deterred by a supposed impossibility of breathing at the top. However, it has been invariably found that the air in the highest that our modern travellers have ascended is not at all too fine for respiration. At the top of the Peak of Teneriffe there was found no other inconvenience from the air except its coldness; at the top of the Andes, there was no difficulty of breathing experienced. The accounts, therefore, of those who have asserted that they were unable to breathe, although at much less heights, are greatly to be suspected. In fact, it is very natural for mankind to paint those obstacles as insurmountable which they themselves have not had the fortitude or perseverance to surmount.

The difficulty and danger of ascending to the tops of mountains proceed from other causes, not the thinness of the air. For instance, some of the summits of the Alps have never yet been visited by man. But the reason is, that they rise with such a rugged and precipitate ascent, that they are utterly inaccessible. In some places they appear like a great wall of six or seven hundred feet high; in others, there stick out enormous rocks, that hang upon the brow of the steep, and every moment threaten destruction to the traveller below.

In this manner almost all the tops of the highest mountains are bare and pointed. And this naturally proceeds from their being so continually assaulted by thunders and tempests. All the earthy substances with which they might have been once covered have for ages been washed away from their summits; and nothing is left remaining but immense rocks, which no tempest has hitherto been able to destroy.

Nevertheless, time is every day and every hour making depredations; and huge fragments are seen tumbling down the precipice, either loosened from the summit by frost or rains, or struck down by lightning. Nothing can exhibit a more terrible picture than one of these enormous rocks, commonly larger than a house, falling from its height, with a noise louder than thunder, and rolling down the side of the mountain. Doctor Plot tells of one in particular, which, being loosened from its bed, tumbled down the precipice, and was partly shattered into a thousand pieces. Notwithstanding, one of the largest fragments of the same, still preserving its motion, travelled over the plain below, crossed a rivulet in the midst, and at last stopped on the other side of the bank! These fragments, as was said, are often struck off by lightning, and sometimes undermined by rains; but the most usual manner in which they are disunited from the mountain is by frost: the rains, insinuating between the interstices of the mountain, continue there until there comes a frost, and then, when converted into ice, the water swells with an irresistible force, and pre-

W. J. Hunt N. Hull

duces the same effect as gunpowder—splitting the most solid rocks, and thus shattering the summits of the mountain.

But not rocks alone, but whole mountains, are by various causes, disunited from each other. We see in many parts of the Alps amazing clefts, the sides of which so exactly correspond with the opposite, that no doubt can be made of there having been once joined together. At Cajeta, in Italy, a mountain was split in this manner by the earthquake; and there is a passage opened through it that appears as if elaborately done by the industry of man. In the Andes these breaches are frequently seen. That at Thermopylæ, in Greece, has been long famous. The mountain of the Troglodytes, in Arabia, has thus a passage through it; and that in Savoy—which Nature began, and which Victor Amadeus completed—is an instance of the same kind.

We have accounts of some of these disruptions immediately after their happening. In the month of June, in the year 1714, a part of the mountain of Diableret, in the district of Valais, in France, suddenly fell down between two and three o'clock in the afternoon, the weather being very calm and serene. It was of a conical figure, and destroyed fifty-five cottages in the fall. Fifteen persons, together with about a hundred beasts, were also crushed beneath its ruins, which covered an extent of a good league square. The dust it occasioned instantly covered all the neighbourhood in darkness. The heaps of rubbish were more than three hundred feet high. They stopped the current of a river that ran along the plain, which now is formed into several new and deep lakes. There appeared through the whole of this rubbish none of those substances that seemed to indicate that this disruption had been made by means of subterranean fires. Most probably the base of this rocky mountain was rotted and decayed, and fell without any extraneous violence. In the same manner, in the year 1618, the town of Pleurs, in France, was buried beneath a rocky mountain, at the foot of which it was situated.

These accidents—and many more that might be enumerated of the same kind—have been produced by various causes; by earthquakes, as in the mountain at Cajeta; or by being decayed at the bottom, as at Diableret. But the most general way is by the foundation of one part of the mountain being hollowed by waters, and thus, wanting a support, breaking from the other. Thus, it generally has been found in the great chasms of the Alps; and thus it almost always is known in those disruptions of hills which are known by the name of land-slips. These are nothing more than the sliding down of a higher piece of ground, disrooted from its situation by subterranean inundations, and settling itself upon the plain below.

There is not an appearance in all Nature that so much astonished our ancestors as these land-slips. In fact, to behold a large upland, with its houses, its corn, and its cattle, at once loosened from its place, and floating, as it were, upon the subjacent water—to behold it quitting its ancient situation, and travelling forward like a ship in quest of adventures,—this is certainly one of the most extraordinary appearances that can be imagined, and, to a people ignorant of the powers of Nature, might well be considered as a prodigy. Accordingly, we find all our old historians mentioning it as an omen of approaching calamities. In this more enlightened age, however, its cause is very well known; and, instead of exciting ominous apprehensions in the populace, it only gives rise to some very ridiculous law-suits among them about whose the property shall be—whether the land which has thus slipped shall belong to the original possessor, or to him upon whose grounds it has encroached and settled. What has been the determination of the judges is not so well known, but the circumstances of the slips have been minutely and exactly described

In the lands of Slatberg, in the kingdom of Iceland, there stood a declivity gradually ascending for nearly half a mile. In the year 1713, on the 10th of March, the inhabitants perceived a crack on its side, somewhat like a furrow made with a plough, which they imputed to the effects of lightning, as there had been thunder the night before. However, on the evening of the same day, they were surprised to hear a hideous, confused noise, issuing all round from the side of the hill; and their curiosity being raised they searched the place. There, to their amazement, they found the earth for nearly five acres all in gentle motion, and sliding down the hill upon the subjacent plain. This motion continued the remaining part of the day and the whole night; nor did the noise cease during the whole time—proceeding, probably, from the attrition of the ground beneath. The day following, however, this strange journey down the hill ceased entirely, and above an acre of the meadow below was found covered with what before composed a part of the declivity.

However, these slips, when a whole mountain's side seems to descend, happen but very rarely. There are some of another kind, however, much more common, and, as they are always sudden, much more dangerous. These are snow-slips—well known and greatly dreaded by travellers. It often happens, that when snow has long been accumulated on the tops and on the sides of mountains, it is borne down the precipice either by means of tempests or its own melting. At first, when loosened, the volume in motion is but small; but it gathers as it continues to roll, and, by the time it has reached the habitable parts of the mountain, is generally grown of enormous bulk. Wherever it rolls it levels all things in its way, or buries them in unavoidable destruction. Instead of rolling, it sometimes is found to slide along from the top; yet even thus it is generally as fatal as before. Nevertheless, we have had an instance, a few years ago, of a small family in Germany that lived for above a fortnight beneath one of these snow-slips. Although they were buried during the whole time, in utter darkness and under a bed of some hundred feet deep, yet they were luckily taken out alive—the weight of the snow being supported by a beam that kept up the roof, and nourishment being supplied them by the milk of an ass (if I remember right) that was buried under the same ruin.

But it is not the parts alone that are thus found to subside; whole mountains have been known totally to disappear. Pliny tells us, that in his own time the lofty mountain of Cybotus, together with the city of Eurites, were swallowed by an earthquake. The same fate, he says, attended Phlegium, one of the highest mountains in Æthiopia; which, after one night's concussion, was never seen more. In more modern times, a very noted mountain in the Molucca Islands, known by the name of the "Peak," and remarkable for being seen at a very great distance from sea, was swallowed by an earthquake, and nothing but a lake was left in the place where it stood. Thus, while storms and tempests are levelled against mountains above, earthquakes and waters are undermining them below. All our histories talk of their destruction; and very few new ones (if we except Mount Cenerè, and one or two such heaps of cinders) are produced. If mountains, therefore, were of such great utility as some philosophers make them to mankind, it would be a very melancholy consideration that such benefits were diminishing every day. But the truth is, the valleys are fertilised by that earth which is washed from their sides, and the plains become richer in proportion as the mountains decay.

## CHAP. XIII.

## OF WATER.

In contemplating Nature, we shall often find the same substances possessed of contrary qualities, and producing opposite effects. Air, which liquifies our substance, dries up another. That fire which is seen to burn up the desert is often found, in other places, to assist the luxuriance of vegetation; and water—which, next to fire, is the most fluid substance upon earth—gives all other bodies their firmness and durability: so that every element seems to be a powerful servant, capable either of good or ill, and only requiring external direction to become the friend or the enemy of mankind. These opposite qualities, in this substance in particular, have not failed to excite the admiration and inquiry of the curious.

That water is the most fluid penetrating body (next to fire), and the most difficult to confine, is incontestibly proved by a variety of experiments. A vessel through which water cannot pass may be said to retain anything. It may be objected, indeed, that syrups, oils, and honey leak through some vessels that water cannot pass through; but this is far from being the result of the greater tenuity and fineness of their parts; it is owing to the resin wherewith the wood of such vessels abounds, which oils and syrups have the power of dissolving—so that these fluids, instead of finding their way, may more properly be said to eat their way through the vessels which contain them. However, water will at length find its way even through these—for it is known to escape through vessels of every substance, glass only excepted. Other bodies may be found to make their way out more readily indeed—as air, when it finds a vent, will escape at once; and quicksilver, because of its weight, quickly penetrates through whatever chinky vessel confines it; but water, though it operates more slowly, always finds a more certain issue. As, for instance, it is well known that air will not pass through leather, which water will very readily penetrate. Air, also, may be retained in a bladder; but water will soon ooze through. And those who drive this to the greatest degree of precision pretend to say that it will pass through pores ten times smaller than air can do. Be this as it may, we are very certain that its parts are so small, that they have been actually driven through the pores of gold. This has been proved by the famous Florentine experiment, in which a quantity of water was shut up in a hollow ball of gold, and then pressed with immense force by screws, during which the fluid was seen to ooze out through the pores of the metal, and to stand like a dew upon its surface.

As water is thus penetrating and its parts thus minute, it may easily be supposed that they enter into the composition of all bodies—vegetable, animal, and fossil. This every chymist's experience convinces him of; and the mixture is the more obvious, as it can always be separated by a gentle heat from those substances with which it had been united. Fire, as was said, will penetrate where water cannot pass; but then it is not so easily separated. But there is scarce any substance from which water cannot be divorced. The parings or filings of lead, tin, and antimony, by distillation, yield water plentifully; the hardest stones, sea-salt, nitre, vitriol, and sulphur, are found to consist chiefly of water, into which they resolve by force of fire. "All birds, beasts, and fishes," says Newton, "insects, trees, and vegetables, with their parts, grow from water, and by putrefaction return to water again." In short, almost every substance that we see owes its texture and firmness to the parts of water that mix with its earth; and, deprived of this fluid, it becomes a mass of shapeless dust and ashes.

From hence we see, as was above hinted, that this

most fluid body, when mixed with others, gives them consistence and form. Water, by being mixed with earth and ashes and formed into a vessel, when baked before the fire becomes a copel, remarkable for this—that it will bear the utmost force of the hottest furnace that art can contrive. So the Chinese earth, of which porcelain is made, is nothing more than an artificial composition of earth and water united by heat, and which a greater quantity of heat could easily separate. Thus we see a body, extremely fluid of itself, in some measure assuming a new nature by being united with others; we see a body, whose fluid and dissolving qualities are so obvious, giving confidence and hardness to all the substances of the earth.

From considerations of this kind, Thales and many of the ancient philosophers held that all things were made of water. In order to confirm this opinion, Helmont made an experiment, by divesting a quantity of earth of all its oils and salts, and then putting this earth, so prepared, into an earthen pot which nothing but rain-water could enter, and planting a willow therein. The willow grew up to a considerable height and bulk, merely from the accidental aspersion of rain-water; while the earth in which it was planted received no sensible diminution. From this experiment he concluded that water was the only nourishment of the vegetable tribe; and that, vegetables being the nourishment of animals, all organised substances therefore owed their support and being only to water. But Woodward says this is all a mistake; and he endeavours to show that water, being impregnated with earthy particles, is only the conveyer of such substances into the pores of vegetables, rather than increaser of them, by its own bulk. He also shows that water is ever found to afford so much less nourishment in proportion as it is putrefied by distillation. A plant in distilled water will not grow so fast as in water not distilled; and if the same be distilled three or four times over, the plant will scarcely grow at all, or receive any nourishment from it—so that water, as such, does not seem the proper nourishment of vegetables, but only the vehicle thereof which contains the nutritious particles, and carries them through all parts of the plant. Water, in its pure state, may suffice to extend or swell the parts of a plant, but affords vegetable matter in a moderate proportion.

However this be, it is agreed on all sides that water, such as we find it, is far from being a pure simple substance. The most genuine we know is mixed with exhalations and dissolutions of various kinds; and no expedient that has been hitherto discovered is capable of purifying it entirely. If we filter and distil it a thousand times, according to Boerhaave, it will still deposit a sediment; and by repeating the process we may evaporate it entirely away, but can never totally remove its impurities. Some, however, assert that water, properly distilled, will have no sediment; and that the little white speck which is found at the bottom of the still is a substance that enters from without. Kircher used to show in his museum a phial of water that had been kept for fifty years hermetically sealed, during which time it had deposited no sediment, but continued as transparent as when first it was put in. How far, therefore, it may be brought to a state of purity by distillation is unknown; but we very well know that all such water as we everywhere see is a bed in which plants, minerals, and animals are found confusedly floating together.

Rain-water, which is a fluid of Nature's own distilling, and which has been raised so high by evaporation, is, nevertheless, a very mixed and impure substance. Exhalations of all kinds, whether salts, sulphurs, or metals, make a part of its substance, and tend to increase its weight. If we gather the water that falls after a thunder-clap in a sultry summer's day, and let it settle, we shall find a real salt sticking at the bottom. In winter, however, its impure mixtures are fewer; but still they

may be separated by distillation. But as to that which is generally caught pouring from the tops of houses, it is particularly foul, being impregnated with the smoke of the chimneys, the vapour of the slates or tiles, and with other impurities that birds and animals may have deposited there. Besides, though it should be supposed free from all these, it is mixed with a quantity of air, which, after being kept for some time, will be seen to separate.

Spring-water is next, in point of purity. This, according to Dr. Halley, is collected from the air itself; which, being sated with water, and coming to be condensed by the evening's cold, is driven against the tops of the mountains, where, being condensed and collected it trickles down by the sides into the cavities of the earth, and, running for a while under-ground, bubbles in fountains upon the plain. This, having made but a short circulation, has generally had no long time to dissolve or imbibe any sovereign substances by the way.

River-water is generally more foul than the former; wherever the stream flows it receives a tincture from its channel. Plants, minerals, and animals, all contribute to add to its impurities: so that such as live at the mouths of great rivers generally are subject to all those disorders which contaminated and unwholesome waters are known to produce. Of all the river-water in the world, that of the Indus and the Thames is said to be the most light and wholesome.

The most impure fresh-water that we know is that of stagnated pools and lakes, which, in summer, may be more properly considered as a jelly of floating insects than a collection of water. In this, millions of little reptiles, undisturbed by any current, which might crush their frames to pieces, breed and engender. The whole teems with shapeless life, and only grows more fruitful by increasing putrefaction.

Of the purity of all these waters, the lightness and not the transparency ought to be the test. Water may be extremely clean and beautiful to the eye, and yet very much impregnated with mineral particles. In fact, sea-water is the most transparent of any, and yet is well known to contain a large mixture of salt and bitumen. On the contrary, those waters which are lightest have the fewest dissolutions floating in them; and may, therefore, be the most useful for all the purposes of life. But, after all, though much has been said upon this subject, and although waters have been weighed with great assiduity to determine their degree of salubrity, yet neither this, nor their curdling with soap, nor any other philosophical standard whatsoever, will answer the purposes of true information. Experience alone ought to determine the useful or noxious qualities of every spring; and experience assures us, that different kinds of water are adapted to different constitutions. An incontestable proof of this are the many medicinal springs throughout the world, whose peculiar benefits are known to the natives of their respective countries. These are of various kinds, according to the different minerals with which they are impregnated—hot, saline, sulphureous, bituminous, and oily. But the account of these will come most properly under that of the several minerals by which they are produced.

After all, therefore, we must be contented with but an impure mixture for our daily beverage. And yet, perhaps, this very mixture may often be more serviceable to our health than that of a purer kind. We know that it is so with regard to vegetables; and why not, also, in general to man? Be this as it will, if we are desirous of having water in its greatest purity, we are ordered by the curious in this particular to distil it from snow, gathered upon the tops of the highest mountains, and to take none but the outer and superficial part thereof. This we must be satisfied to call pure water; but even this is far short of the pure unmixed philosophical element—which, in reality, is no where to be found.

As water is thus mixed with foreign matter, and often the repository of minute animals or vegetable seeds, we need not be surprised that, when carried to sea, it is always found to putrefy. But we must not suppose that it is the element itself which thus grows putrid and offensive, but the substances with which it is impregnated. It is true, the utmost precautions are taken to destroy all vegetable and animal substances that may have previously been lodged in it, by boiling; but, notwithstanding this, there are some that will still survive the operation, and others that find their way during the time of its stowage. Seamen assure us that their water is generally found to putrefy twice at least, and sometimes thrice, in a long voyage. In about a month after it has been at sea, when the bung is taken out of the cask, it sends up a noisome and dangerous vapour, which takes fire upon the application of a lighted candle. The whole body of the water is then found replete with little worm-like insects, which float with great briskness through all its parts. These generally live for about a couple of days; and then dying, by depositing their spoils for a while increase the putrefaction. After a time, the heavier parts of these sinking to the bottom, the lighter float in a scum at the top; and this is what the mariners call the water's purging itself. There is still, however, another race of insects, which are bred very probably from the spoils of the former, and produce, after some time, similar appearances; these dying, the water is then thought to change no more. However, it very often happens, especially in hot climates, that nothing can drive these nauseous insects from the ship's store of water. They often increase to a very disagreeable and frightful size, so as to deter the mariner, though parching with thirst, from tasting that cup which they have contaminated.

This water, as thus described, is therefore a very different fluid from that simple elementary substance upon which philosophical theories have been founded, and concerning the nature of which there have been so many disputes. Elementary water is no way compounded, but is without taste, smell, or colour, and incapable of being discerned by any of the senses except the touch. This is the famous dissolvent of the chymists, into which, as they have boasted, they can reduce all bodies, and which makes up all other substances, only by putting on a different disguise. In some forms it is fluid, transparent, and evasive of the touch; in others, hard, firm, and elastic. In some it is stiffened by cold; in others, dissolved by fire. According to them, it only assumes external shapes from accidental causes; but the mountain is as much a body of water as the cake of ice that melts on its brow; and even the philosopher himself is composed of the same materials with the cloud or meteor which he contemplates.

Speculation seldom rests when it begins. Others, disallowing the universality of this substance, will not allow that in a state of nature there is any such thing as water at all. "What assumes the appearance," say they, "is nothing more than melted ice. Ice is the real element of Nature's making; and when found in a state of fluidity it is then in a state of violence. All substances are naturally hard; but some more readily melt with heat than others. It requires a great heat to melt iron—a smaller heat will melt copper; silver, gold, tin, and lead, melt with smaller still; ice, which is a body like the rest, melts with a very moderate warmth; and quicksilver melts with the smallest warmth of all. Water, therefore, is but ice kept in continual fusion, and still returning to its former state when the heat is taken away." Between these opposite opinions the controversy has been carried on with great ardour, and much has been written on both sides; and yet, when we come to examine the debate, it will probably terminate in this question—whether cold or heat first began their operations upon water. This is a fact of very little

importance, if known; and, what is more, it is a fact we can never know.

Indeed, if we examine into the operations of cold and heat upon water, we shall find that they produce somewhat similar effects. Water dilates in its bulk by heat to a very considerable degree; and, what is more extraordinary, it is likewise dilated by cold in the same manner.

If water be placed over a fire, it grows gradually larger in bulk as it becomes hot, until it begins to boil; after which no art can either increase its bulk or its heat. By increasing the fire, indeed, it may be more quickly evaporated away; but its heat and its bulk still continue the same. By the expanding of this fluid by heat, philosophers have found a way to determine the warmth or the coldness of other bodies; for if put into a glass tube, by its swelling and rising it shows the quantity of heat in the body to which it is applied; by its contracting and sinking, it shows the absence of the same. Instead of using water in this instrument, which is called a thermometer, they now make use of spirit of wine, which is not apt to freeze, and which is endued even with a greater expansion by heat than water. The instrument consists of nothing more than a hollow ball of glass, with a long tube growing out of it. This being partly filled with spirits of wine, tintured red, so as to be seen when it rises, the ball is plunged into boiling water, which, making the spirit within expand and rise in the tube, the water marks the greatest height to which it ascends; at this point the tube is to be broken off, and then hermetically sealed by melting the glass with a blow-pipe; a scale being placed by the side completes the thermometer. Now, as the fluid expands or condenses with heat or cold, it will rise and fall in the tube in proportion, and the degree or quantity of ascent or descent will be seen in the scale.

No fire, as was said, can make water hotter after it begins to boil. We can therefore at any time be sure of an equable certain heat—which is that of boiling water, which is invariably the same. The certainty of such a heat is not less useful than the instrument that measures it. It affords a standard, fixed degree of heat over the whole world—boiling water being as hot in Greenland as upon the coasts of Guinea. One fire is more intense than another; of heat there are various degrees; but boiling water is a heat every where the same, and easily procurable.

As heat thus expands water, so cold, when it is violent enough to freeze the same, produces exactly the same effect, and expands it likewise. Thus water is acted upon in the same manner by two opposite qualities—being dilated by both. As a proof that it is dilated by cold, we have only to observe the ice floating on the surface of a pond, which it would not do were it not dilated, and grown more bulky by freezing than the water which remains unfrozen. Mr. Boyle, however, put the matter past a doubt by a variety of experiments. Having poured a proper quantity of water into a strong earthen vessel, he exposed it, uncovered, to the open air in frosty nights, and observed that continually the ice reached higher than the water before it was frozen. He filled also a tube with water, and stopped both ends with wax; the water, when froze, was found to push out the stopples from both ends, and a rod of ice appeared at each end of the tube, which showed how much it was swollen by the cold within.

From hence, therefore, we may be very certain of the cold's dilating of the water; and experience also shows, that the force of this expansion has been found as great as any which heat has been found to produce. The touch-hole of a strong gun-barrel being stopped, and a plug of iron forcibly driven into the muzzle, after the barrel had been filled with water it was placed in a mixture of ice and salt; the plug, though soldered to the barrel, at first gave way, but being fixed in more firmly, within a

quarter of an hour the gun-barrel burst with a loud noise, and blew up the cover of the box wherein it lay. Such is its force in an ordinary experiment. But it has been known to burst cannons, filled with water and then left to freeze; for the cold congealing the water, and the ice swelling, it became irresistible. The bursting of rocks by frost, which is frequent in the northern climates, and is sometimes seen in our own, is an equal proof of the expansion of congealed water. For having by some means insinuated itself into the body of the rock, it has remained there till the cold was sufficient to affect it by congelation. But when once frozen, no obstacle is able to confine it from dilating; and, if it cannot otherwise find room, the rock must burst asunder.

This alteration in the bulk of water might have served as a proof that it was capable of being compressed into a narrower space than it occupied before; but, till of late, water was held to be incompressible. The general opinion was, that no art whatsoever could squeeze into a narrower compass; that no power on earth, for instance, could force a pint of water into a vessel that held a hair's-breadth less than a pint. This, said they, appears from the famous Florentine experiment, as the water, rather than suffer compressure, was seen to ooze through the pores of the solid metal; and at length, making a cleft in the side, spun out with great vehemence. Later trials have proved that water is very compressible, and partakes of that elasticity which every other body possesses in some degree. Indeed, had not mankind been dazzled by the brilliancy of one inconclusive experiment, there were numerous reasons to convince them of its having the same properties with other substances. Ice, which is water in another state, is very elastic. A stone flung slantingly along the surface of a pond bounds from the water several times, which shows it to be elastic also. But the trials of Mr. Canton have put this past all doubt; which, being somewhat similar to those of the great Boyle, who pressed it with weights properly applied, carry sufficient conviction.

What has been hitherto related is chiefly applicable to the element of water alone; but its fluidity is a property that it possesses in common with several other substances, in other respects greatly differing from it. That quality which gives rise to the definition of a fluid—namely, that its parts are in a continual intestine motion—seems extremely applicable to water. What the shapes of those parts are it would be vain to attempt to discover. Every trial only shows the futility of the attempt: all we find is that they are extremely minute, and that they roll over each other with the greatest ease. Some, indeed, from this property alone, have not hesitated to pronounce them globular; and we have in all our hydrostatical books pictures of these little globes in a state of sliding and rolling over each other. But all this is merely the work of imagination: we know that substances of any kind, reduced very small, assume a fluid appearance somewhat resembling that of water. Mr. Boyle, after finely powdering and sifting a little dry powder of plaster of Paris, put it in a vessel over the fire, where it soon began to boil like water, exhibiting all the motions and appearances of a boiling liquor. Although but a powder, the parts of which we know are very different from each other, and just as accident has formed them, yet it heaved in great waves, like water. Upon agitation, a heavy body will sink to the bottom, and a light one emerge to the top. There is no reason, then, to suppose the figure of the parts of water round, since we see their fluidity very well imitated by a composition the parts of which are of various forms and sizes. The shape of the parts of water, therefore, we must be content to continue ignorant of. All we know is, that earth, air, and fire conduce to separate the parts from each other.

Earthy substances divide the parts from each other, and keep them asunder. This division may be so great,

that the water will entirely lose its fluidity thereby. Mud, potters' clay, and dried bricks are but so many different combinations of earth and water—each substance in which the parts of water are most separated from each other appearing to be the most dry. In some substances, indeed, where the parts of water are greatly divided, as in porcelain, for instance, it is no easy matter to recover and bring them together again; but they continue in a manner fixed and united to the manufactured clay. This circumstance led Dr. Cheney into a very peculiar strain of thinking. He suspected that the quantity of water on the surface of the earth was daily increasing. For, says he, some parts of it are continually joined to vegetable, animal, and mineral substances, which no art can again recover. United with these the water loses its fluidity; for if, continues he, we separate a few particles of any fluid and fasten them to a solid body, or keep them assunder, they will be fluid no longer. To produce fluidity a considerable number of such particles are required; but here they are close, and destitute of their natural properties. Thus, according to him, the world is growing every day harder and harder, and the earth firmer and firmer; and there may come a time when every object around us may be stiffened in universal frigidity! However, we have causes enough of anxiety in this world already, not to add this preposterous concern to the number.

That air also contributes to divide the parts of water we can have no manner of doubt; some have even disputed whether water be not capable of being turned into air! However, though this cannot be allowed, it must be granted that it may be turned into a substance which greatly resembles air (as we have seen in the experiment of the *œolipile*) with all its properties—except that, by cold, this new-made air may be condensed again into water.

But of all the substances which tend to divide the parts of water, fire is the most powerful. Water, when heated into steam, acquires such force, and the parts of it tend to fly off from each other with such violence, that no earthly substance we know of is strong enough to confine them. A single drop of water converted into steam has been found capable of raising a weight of twenty tons; and would have raised twenty thousand were the vessel confining it sufficiently strong, and the fire below increased in proportion.

From this easy yielding of its parts to external pressure arises the art of determining the specific gravity of bodies by plunging them in water; with many other useful discoveries in that part of natural philosophy, called "hydrostatics." The laws of this science, which Archimedes began, and Pascal, with some other of the moderns, have much improved, rather belongs to experimental than to natural history. However, I will take leave to mention some of the most striking paradoxes in this branch of science, which are well confirmed by experiment as rendered universal by theory. It would indeed, be unpardonable, while discoursing on the properties of water, to omit giving some account of the manner in which it sustains such immense bulks as we see floating upon its soft and yielding surface; how some bodies that are known to sink at one time swim with ease, if their surface be enlarged; how the heaviest body, even gold itself, may be made to swim upon water, and how the lightest, such as cork, shall remain sunk at the bottom; how the pouring in of a single quart of water will burst a hogshead hooped with iron; and how it ascends in pipes from the valley to travel over the mountain:—these are circumstances that are at first surprising, but, upon a slight consideration, lose their wonder.

In order to conceive the manner in which all these wonders are effected, we must begin by observing that water is possessed of an invariable property, which has not hitherto been mentioned—that of always keeping

its surface level and even. Winds, indeed, may raise it into waves, or art spurt it 'up in fountains; but ever, when left to itself it sinks into a smooth even surface, of which no one part is higher than another. If I should pour water, for instance, into the arm of a pipe of the shape of the letter U, the fluid would rise in the other arm just to the same height; because, otherwise, it would not find its level, which it invariably maintains. A pipe bending from one hill down into the valley, and rising by another, may be considered as a tube of this kind, in which the water, sinking in one arm, rises to maintain its level in the other. Upon this principle all water-pipes depend, which can never raise the water higher than the fountain from which they proceed.

Again, let us suppose for a moment that the arms of the pipe already mentioned may be made long or short at pleasure; and let us still further suppose that there is some obstacle at the bottom of it which prevents the water pouring into one arm from rising in other. Now, it is evident that this obstacle at the bottom will sustain a pressure from the water in one arm equal to what would make it rise in the other; and this pressure will be great in proportion as the arm filled with water is tall. We may therefore generally conclude that the bottom of every vessel is pressed by a force in proportion to the height of the water in that vessel. For instance, if the vessel filled with water be forty feet high, the bottom of that vessel will sustain such a pressure as would raise the same water forty feet high, which is very great. From hence we see how extremely apt our pipes that convey water to the city are to burst; for descending from a hill of more than forty feet high, they are pressed by the water contained in them with a force equal to what would raise it more than forty feet high; and that this is sometimes able to burst a wooden pipe we can have no room to doubt.

Still recurring to our pipe, let us suppose one of its arms ten times as thick as the other; this will produce no effect whatsoever upon the obstacle below, which we supposed hindering its rise in the other arm; because how thick soever the pipe may be, its contents would only rise to its own level; and it will, therefore, press the obstacle with a force equal thereto. We may therefore universally conclude that the bottom of any vessel is pressed by its water, not as it is broad or narrow, but in proportion as it is high. Thus, the water contained in a vessel not thicker than my finger presses its bottom as forcibly as the water contained in a hogshead of an equal height; and if we made holes in the bottoms of both, the water would burst out as forcibly from the one as the other. Hence we may easily burst a hogshead with a single quart of water; and it has been often done. We have only to place a hogshead on one end filled with water; we then bore a hole in its top, into which we plant a narrow tin pipe of about thirty feet high; by pouring a quart of water into this at the top, as it continues to rise higher in the pipe it will press more forcibly on the bottom and sides of the hogshead below, and at last burst it.

Still returning to our simple instrument of demonstration. If we suppose the obstacle at the bottom of the pipe to be moveable, so as that the force of the water can push it up into the other arm; such a body is quicksilver, for instance. Now, it is evident that the weight of water weighing down upon this quicksilver in one arm will at last press it up in the other arm, and will continue to press it upward until the fluid in both arms be upon a par; so that here we actually see quicksilver, the heaviest substance in the world except gold, floating upon water, which is but a very light substance.

When we see water thus capable of sustaining quicksilver, we need not be surprised that it is capable of floating much lighter substances—ships, animals, or timber. When anything floats upon water, we always see that a part of it sinks in the same. A cork, a ship,

a buoy, each buries itself a bed on the surface of the water. This bed may be considered as so much water displaced; the water will therefore lose so much of its own weight as is equal to the weight of that bed of water which it displaces. If the body be heavier than a similar bulk of water, it will sink; if lighter, it will swim. Universally, therefore, a body plunged in water loses as much of its weight as is equal to the weight of a body of its own bulk. Some light bodies, therefore, such as cork, lose much of their weight, and therefore swim; and more ponderous bodies sink, because they are heavier than their bulk of water.

Upon this simple theorem entirely depends the art of weighing metals hydrostatically. I have a guinea, for instance, and desire to know whether it be pure gold: I have weighed it in the usual way with another guinea, and find it exactly of the same weight, but still I have some suspicion, from its great bulk, that it is not pure. In order to determine this, I have nothing more to do than to weigh it in water with that same guinea that I know to be good, and of the same weight; and this will instantly show the difference; for the true ponderous metal will sink, and the false bulky one will be sustained in proportion to the greatness of its surface. Those whose business it is to examine the purity of metals have a balance made for this purpose, by which they can precisely determine which is most ponderous or, as it is expressed, which has the greatest specific gravity. Seventy-one pounds and a half of quicksilver is found to be equal in bulk to a hundred pounds weight of gold. In the same proportion, sixty of lead, fifty-four of silver, forty-seven of copper, forty-five of brass, forty-two of iron, and thirty-nine of tin, are each equal to a hundred pounds of the same ponderous of all metals.

This method of precisely determining the purity of gold by weighing in water was first discovered by Archimedes, to whom mankind have been indebted for many useful discoveries. Hiero, king of Sicily, having sent a certain quantity of gold to be made into a crown, the workman, it seems, kept a part for his own use, and supplied the deficiency with a baser metal. His fraud was suspected by the king, but could not be detected; till applying to Archimedes, he weighed the crown in water; and by this method informed the king of the quantity of gold which was taken away.

It has been said that all fluids endeavour to preserve their level; and, likewise, that a body pressing on the surface tended to destroy that level. From hence, therefore, it will easily be inferred that the deeper any body sinks the greater will be the resistance of the depressed fluid beneath. It will be asked, therefore, as the resistance increases in proportion as the body descends—How comes the body after it is got a certain way to sink at all? The answer is obvious; from the fluid above pressing it down with almost as great a force as the fluid beneath presses it up. Take away by any art the pressure of the fluid from above, and let only the resistance of the fluid from below be suffered to act; and after the body is got down very deep the resistance will be insuperable. To give an instance. A small hole opens in the bottom of a ship at sea, forty feet, we will suppose, below the surface of the water; through this the water bursts up with great violence; I attempt to stop it with my hand, but it pushes the hand violently away. Here the hand is, in fact, a body attempting to sink upon water, at a depth of forty feet, with the pressure from above taken away. The water, therefore, will overcome my strength, and it will continue to burst in till it has got to its level; if I should then dive into the hold, and clap my hand upon the opening as before, I should perceive no force acting against my hand at all; for the water above presses the hand as much down against the hole as the water without presses it upward. For this reason, also, when we dive to the bottom of the water we sustain a very great pressure from above, it is true, but it is coun-

teracted by the pressure from below; and the whole acting uniformly on the surface of the body, wraps us close round without injury.

As I have deviated thus far, I will just mention one or two properties more which water and all such like fluids is found to possess. And first, their ascending in vessels which are emptied of air, as in our common pumps, for instance. The air, however, being the agent in this case, we must previously examine its properties before we undertake the explanation. The other property to be mentioned is that of their ascending in small capillary tubes. This is one of the most extraordinary and inscrutable appearances in nature. Glass tubes may be drawn, by means of a lamp, as fine as a hair—still preserving their hollow within. If one of these be planted in a vessel of water or spirit of wine, the liquor will immediately be seen to ascend; and it will rise higher, in proportion as the tube is smaller, a foot, two feet, and more. How does this come to pass? Is the air the cause? No; the liquor rises although the air be taken away. Is attraction the cause? No; for quicksilver does not ascend, which it otherwise would. Many have been the theories of experimental philosophers to explain this property. Such as are fond of travelling in the regions of conjecture may consult Hawkebee, Morgan, Jurin, or Watson, who have examined the subject with great minuteness. Hitherto, however, nothing but doubts instead of knowledge have been the result of their inquiries. It will not, therefore, become us to enter into the minuteness of the inquiry, when we have so many greater wonders to call our attention away

#### CHAP. XIV.

##### OF THE ORIGIN OF RIVERS

"The sun ariseth, and the sun goeth down, and pants for the place from whence he arose—All things are filled with labour, and man cannot utter it. All rivers run into the sea, yet the sea is not full. Unto the place whence the rivers come, thither they return again. The eye is not satisfied with seeing, nor the ear with hearing." Thus speaks the wisest of the Jews; and at so early a period was the curiosity of man employed in observing these great circulations of Nature. Every eye attempted to explain those appearances; and every philosopher who has long thought upon the subject seems to give a peculiar solution. The inquiry whence rivers are produced—whence they derive those unceasing stores of water which continually enrich the world with fertility and verdure—has been variously considered, and divided the opinions of mankind more than any other topic in natural history.

In this contest the various champions may be classed under two leaders, M. De La Hire, who contends that rivers must be supplied from the sea, strained through the pores of the earth; and Dr. Halley, who has endeavoured to demonstrate that the clouds are sufficient for the supply. Both sides have brought mathematics to their aid, and have shown that long and laborious calculations can at any time be made to obscure both sides of a question.

De La Hire begins his proofs that rain-water evaporated from the sea is insufficient for the production of rivers, by showing that rain never penetrates the surface of the earth above sixteen inches. From thence he infers, that it is impossible in many cases for it to sink so as to be found at such considerable depths below. Rain-water he grants is often seen to mix with rivers, and to swell their currents; but a much greater part of it evaporates. "In fact," continues he, "if we suppose the earth everywhere covered with water, evaporation

alone would be sufficient to carry off two feet nine inches of it in a year; and yet we very well know that scarce nineteen inches of rain falls in that time—so that evaporation would carry off a much greater quantity than is ever known to descend. The small quantity of rain-water that falls is therefore but barely sufficient for the purposes of vegetation. Two leaves of a fig-tree have been found by experiment to imbibe from the earth, in five hours and a half, two ounces of water. This implies the great quantity of fluid that must be exhausted in the maintenance of one single plant. Add to this, that the waters of the river Rungis will, by calculation, rise to fifty inches; and the whole country from whence they are supplied never receives fifty inches in the year by rain. Besides this, there are many salt springs which are known to proceed immediately from the sea, and are subject to its flux and reflux. In short, wherever we dig beneath the surface of the earth, except in very few instances, water is to be found; and it is by this subterraneous water that springs and rivers, nay, a great part of vegetation itself, is supported; it is this subterraneous water which is raised into steam by the internal heat of the earth that feeds plants; it is this subterraneous water that distils through its interstices, and there, cooling, forms fountains; it is this, that, by the addition of rains, is increased into rivers, and pours plenty over the whole earth."

On the other side of the question, it is asserted that the vapours which are exhaled from the sea, and driven by the winds upon land, are more than sufficient to supply not only plants with moisture, but also to furnish a sufficiency of water to the greatest rivers. For this purpose, an estimate has been made of the quantity of water emptied at the mouths of the greatest rivers, and of the quantity also raised from the sea by evaporation; and it has been found that the latter by far exceeds the former. This calculation was made by Mr. Marionet. By him it was found, upon receiving such rain as fell in a year, in a proper vessel fitted for that purpose, that, one year with another, there might fall about twenty inches of water upon the surface of the earth throughout Europe. It was also computed that the river Seine, from its source to the city of Paris, might cover an extent of ground that would supply it annually with above seven billions of cubic feet of this water formed by evaporation. But upon computing the quantity which passed through the arches of one of its bridges in a year, it was found to amount only to two hundred and eighty millions of cubic feet, which is not above the sixth part of the former number. Hence, therefore, it appears that this river may receive a supply, brought to it by the evaporated waters of the sea, six times greater than what it gives back to the sea by its current; and, therefore, evaporation is more than sufficient for maintaining the greatest rivers, and supplying the purposes also of vegetation.

In this manner the sea supplies sufficient humidity to the air for furnishing the earth with all necessary moisture. One part of its vapours fall upon its own bosom before they arrive upon land. Another part is arrested by the sides of the mountains, and is compelled, by the rising stream of air, to mount upward towards its summits. Here it is presently precipitated, dripping down by the crannies of the stone. In some places, entering into the caverns of the mountains, it gathers in those receptacles, which, being once filled, all the rest overflows, and, breaking out by the sides of the hills, forms single springs. Many of these run down by the valleys or guts between the ridges of the mountain, and, coming to unite, form little rivulets or brooks; many of these, meeting in one common valley, and gaining the plain ground, being grown less rapid, become a river; and many of these uniting, make such vast bodies of water as the Rhine, the Rhone, and the Danube.

There is still a third part, which falls upon the lower

grounds, and furnishes plants with their wonted supply. But the circulation does not even rest here; for it is again exhaled into vapour by the action of the sun, and afterward returned to that great mass of waters whence it first arose. "This," adds Dr Halley, "seems the most reasonable hypothesis; and much more likely to be true than that of those who derive all springs from the filtering of the sea-waters, through certain imaginary tubes or passages within the earth; since it is well known that the greatest rivers have their most copious fountains the most remote from the sea."

This seems the most general opinion; and yet after all, it is still pressed with great difficulties, and there is still room to look out for a better theory. The perpetuity of many springs which always yield the same quantity when the least rain or vapour is afforded as well as when the greatest, is a strong objection. Derham mentions a spring, at Upminster, which he could never perceive by his eye to be diminished in the greatest droughts, even when all the ponds in the country, as well as an adjoining brook, have been dry for several months together. In the rainy seasons, also, it was never overflowed—except sometimes, perhaps, for an hour or so, upon the immission of the external rains. He therefore justly enough concludes, that had this spring its origin from rain or vapour, there would be found an increase or decrease of its water corresponding to the causes of its production.

Thus the reader, after having been tossed from one hypothesis to another, must at last be content to settle in conscious ignorance. All that has been written upon this subject affords him rather something to say than something to think—something rather for others than for himself. Varenus, indeed, although he is at a loss for the origin of rivers, is by no means so as to their formation. He is pretty positive that all rivers are artificial. He boldly asserts that their channels have been originally formed by the industry of man. His reasons are, that when a new spring breaks forth the water does not make itself a new channel, but spreads over the adjacent land. "Thus," says he, "men are obliged to direct its course, otherwise Nature never would have found one." He enumerates many rivers that are certainly known from history to have been dug by men. He alleges that no salt-water rivers are found, because men did not want salt water; and as for salt, that was procurable at a less expense than digging a river for it. However, it costs a speculative man but a small expense of thinking to form such an hypothesis. It may, perhaps, engross the reader's patience to detain him longer upon it.

Nevertheless, though Philosophy be thus ignorant as to the production of rivers, yet the laws of their motion and the nature of their currents have been very well explained. The Italians have particularly distinguished themselves in this respect, and it is chiefly to them that we are indebted for the improvement.

All rivers have their source either in mountains or elevated lakes; and it is in their descent from these that they acquire that velocity which maintains their future current. At first their course is generally rapid and headlong; but it is retarded in its journey by the continual friction against its banks by the many obstacles it meets to divert its stream, and by the plains generally becoming more level as it approaches towards the sea.

If this acquired velocity be quite spent, and the plain through which the river passes is entirely level, it will, notwithstanding, still continue to run from the perpendicular pressure of the water, which is always in exact proportion to the depth. This perpendicular pressure is nothing more than the weight of the upper waters pressing the lower out of their places, and, consequently, driving them forward, they cannot recede against the stream. As this pressure is greatest

in the deepest parts of the river, so we generally find the middle of the stream most rapid; both because it has the greatest motion thus communicated by the pressure, and the fewest obstructions from the banks on either side.

Rivers thus set into motion are almost always found to make their own beds. Where they find the bed elevated they wear its substance away, and deposit the sediment in the next hollow, so as in time to make the bottom of their channels even. On the other hand, the water is continually gnawing and eating away the banks on each side; and this with more force as the current happens to strike more against them. By these means, it always has a tendency to render them more straight and parallel to its own course. Thus it continues to rectify its banks and enlarge its bed; and, consequently, to diminish the force of its stream, till there becomes an equilibrium between the force of the water and the resistance of its banks, upon which both will remain without any further mutation: and it is happy for man that bounds are put to the erosion of the earth by water, and that we find all rivers only dig and widen themselves but to a certain degree.

In those plains and large valleys where great rivers flow, the bed of the river is usually lower than any part of the valley. But it often happens that the surface of the water is higher than many of the grounds that are adjacent to the banks of the stream. If, after inundations, we take a view of some rivers, we shall find their banks appear above water at a time that all the adjacent valley is overflowed. This proceeds from the frequent deposition of mud and such like substances upon the banks, by the rivers frequently overflowing; and thus, by degrees, they become elevated above the plain; and the water is often seen higher also.

Rivers, as every body has seen, are always broadest at the mouth, and grow narrower towards their source. But what is less known, and probably more deserving curiosity, is, that they run in a more directed channel as they immediately leave their sources; and that their sinuosities and turnings become more numerous as they proceed. It is a certain sign among the savages of North America, that they are near the sea when they find the rivers winding, and every now and then changing their direction. And this is even now become an indication to the Europeans themselves in their journeys through those trackless forests. As those sinuosities, therefore, increase as the river approaches the sea, it is not to be wondered at that they sometimes divide, and thus disembogue by different channels. The Danube disembogues into the Euxine by seven mouths; the Nile by the same number; and the Wolga by seventy.

The currents of rivers are to be estimated very differently from the manner in which those writers who have given us mathematical theories on this subject represent them. They found their calculations upon the surface being a perfect plain from one bank to the other: but this is not the actual state of Nature; for rivers in general rise in the middle; and this convexity is greatest in proportion as the rapidity of the stream is greater. Any person to be convinced of this need only lay his eye as nearly as he can on a level with the stream, and, looking across to the opposite bank, he will perceive the river in the midst to be elevated considerably above what it is at the edges. This rising in some rivers is often found to be three feet high, and is ever increased in proportion to the rapidity of the stream. In this case, the water in the midst of the current loses a part of its weight from the velocity of its motion; while that at the sides, for the contrary reason, sinks lower. It sometimes, however, happens that this appearance is reversed; for when tides are found to flow up with violence against the natural current of the water, the greatest rapidity is then found at the sides of the river, as the water there least resists the influx from the sea.

On those occasions, therefore, the river presents a concave rather than a convex surface; and as in the former case the middle waters rose in a ridge, in this case they sink in a furrow.

The stream in all rivers is more rapid in proportion as its channel is diminished. For instance, it will be much swifter where it is ten yards broad than where it is twenty; for the force behind still pushing the water forward, when it comes to the narrow part it must make up by velocity what it wants in room.

It often happens that the stream of a river is opposed by one of its jutting banks by an island in the midst, the arches of a bridge, or some such obstacle. This produces not unfrequently a back current; and the water, having passed the arch with great velocity, pushes the water on each side of its direct current. This produces a side current, tending to the bank; and not unfrequently a whirlpool, in which a large body of waters are circulated in a kind of cavity sinking down in the middle. The central point of the whirlpool is always lowest, because it has the least motion; the other parts are supported in some measure by the violence of theirs, and consequently rise higher as their motion is greater; so that towards the extremity of the whirlpool must be higher than towards the centre.

If the stream of a river be stopped at the surface, and yet be free below—for instance, if it be laid over by a bridge of boats—there will then be a double current; the water at the surface will flow back, while that at the bottom will proceed with increased velocity. It often happens that the current at the bottom is swifter than at the top, when, upon violent land-floods, the weight of waters towards the source presses the waters at the bottom before it has had time to communicate its motion to the surface. However, in all other cases, the surface of the stream is swifter than the bottom, as it is not retarded by rubbing over the bed of the river.

It might be supposed that bridges, dams, and other obstacles in the current of a river, would retard its velocity. But the difference they make is very inconsiderable. The water, by these stoppages, gets an elevation above the object; which, when it has surmounted them, gives a velocity that recompenses the former delay. Islands and turnings also retard the course of the stream but very inconsiderably; any cause which diminishes the quantity of the water most sensibly diminishes the force and the velocity of the stream.

An increase of water in the bed of the river always increases its rapidity, except in cases of inundation. The instant the river has overflowed its banks the velocity of its current is always turned that way, and the inundation is perceived to continue for some days; which it would not otherwise do if, as soon as the cause was discontinued, it acquired its former rapidity.

A violent storm that sets directly up against the course of the stream will always retard, and sometimes entirely stop its course. I have seen an instance of this, when the bed of a large river was left entirely dry for some hours, and the fish were caught among the stones at the bottom.

Inundations are generally greater towards the source of rivers than farther down, because the current is generally swifter below than above—and that for the reasons already assigned.

A little river may be received into a large one without augmenting either its width or depth. This, which at first view seems a paradox, is yet very easily accounted for. The little river, in this case, only goes towards increasing the swiftness of the larger, and putting its dormant waters into motion. In this manner, the Venetian branch of the Po was pushed on by the Ferrarese branch and that of Panaro, without any enlargement of its breadth or depth from these accessions.

A river tending to enter another, either perpendicularly or in any opposite direction, will be diverted by degrees

from that direction, and be obliged to make itself a more favourable entrance downward, and more conspiring with the stream of the former.

The union of two rivers into one makes it flow the swifter; since the same quantity of water, instead of rubbing against four shores, now only rubs against two. And, besides, the current being deeper, becomes of consequence more fitted for motion.

With respect to the places from whence rivers proceed, it may be taken for a general rule, that the largest and highest mountains supply the greatest and most extensive rivers. It may be also remarked, in whatever direction the ridge of the mountain runs, the river takes an opposite course. If the mountain, for instance, stretches from north to south, the river runs from east and west, and so contrariwise. These are some of the most generally received opinions regarding the course of rivers. However, they are liable to many exceptions; and nothing but an actual knowledge of each particular river can furnish us with an exact theory of its current.

The largest rivers of Europe are, first, the Volga, which is about six hundred and fifty leagues in length, extending from Reeschow to Astrachan. It is remarkable of this river, that it abounds with water during the summer months of May and June; but all the rest of the year is so shallow as to scarce cover its bottom, or allow a passage for loaded vessels that trade up in its stream.

The largest rivers of Africa are, in Senegal, which runs a course of not less than eleven hundred leagues, comprehending the Niger, which some have supposed to fall into it. However, later accounts affirm that the Niger is lost in the sands, about three hundred miles up from the western coasts of Africa. Be this as it may, the Senegal is well known to be navigable for more than three hundred leagues up the country; and how much higher it may reach is not yet discovered, as the dreadful fatality of the inland parts of Africa not only deter curiosity, but even avarice, which is a much stronger passion. At the end of the last war, of fifty Englishmen that were sent to the factory at Galam, a place taken from the French, and nine hundred miles up the river, only one returned to tell the fate of his companions, who were destroyed by the climate. The celebrated river Nile is said to be nine hundred and seventy leagues, from its source among the mountains of the Moon, in Upper Æthiopia, to its opening into the Mediterranean Sea. The sources of this river were considered as inscrutable by the ancients; and the causes of its periodical inundation were equally unknown. They have both been ascertained by the missionaries who have travelled into the interior parts of Æthiopia. The Nile takes its rise in the kingdom of Gojam, from a small aperture on the top of a mountain, which, though not above a foot and a half over, yet was unfathomable. This fountain, when arrived at the foot of the mountain, expands into a river; and, being joined by others, forms a lake thirty leagues long, and as many broad; from this, its channel, in some measure, winds back to the country where it first began; from thence, precipitating by frightful cataracts, it travels through a variety of desert regions, equally formidable, such as Amhara, Olsea, Damot, and Xaoa. Upon its arrival in the kingdom of Upper Egypt, it runs through a rocky channel, which some late travellers have mistaken for its cataracts. In the beginning of its course, it receives many lesser rivers into it; and Pliny was mistaken in saying that it received none. In the beginning also of its course, it has many windings; but, for above three hundred leagues from the sea, it runs in a direct line. Its annual overflowings arise from a very obvious cause, which is almost universal with the great rivers that take their source near the line. The rainy season, which is periodical in those climates, flood the rivers; and as this always happens in our summer, so the Nile is at that time overflowed.

From these inundations, the inhabitants of Egypt derive happiness and plenty; and, when the river does not arise to its accustomed heights, they prepare for an indifferent harvest. It begins to overflow about the seventeenth of June; it generally continues to augment for forty days, and decreases in about as many more. The time of increase and decrease, however, is much more inconsiderable now than it was among the ancients. Herodotus informs us, that it was a hundred days rising, and as many falling; which shows that the inundation was much greater at that time than at present. Mr. Buffon has ascribed the present diminution, as well to the lessening of the Mountains of the Moon, by their substance having so long been washed down with the stream, as to the rising of the earth in Egypt, that had for so many ages received this extraneous supply. But we do not find, by the buildings that have remained since the times of the ancients, that the earth is much raised since then. Besides the Nile in Africa, we may reckon the Zara, and the Ouanza, from the greatness of whose openings into the sea, and the rapidity of whose streams, we form an estimate of the great distance from whence they come. Their courses, however, are spent in watering deserts and savage countries, whose poverty or fierceness have kept strangers away.

But of all parts of the world, America, as it exhibits the most lofty mountains, so also it supplies the largest rivers. The foremost of these is the great river Amazon, which, from its source in the lake of Dauricocha to its discharge into the Western Ocean, performs a course of more than twelve hundred leagues. The breadth and depth of this river is answerable to its vast length; and, where its width is more contracted, its depth is augmented in proportion. So great is the body of its waters, that other rivers, though before the objects of admiration, are lost in its bosom. It proceeds, after their junction, with its usual appearance, without any visible change in its breadth or rapidity; and, if we may so express it, remains without ostentation. In some places it displays its whole magnificence, dividing into several large branches, and encompassing a multitude of islands; and, at length, discharging itself into the ocean by a channel of a hundred and fifty miles broad. Another river, that may almost rival the former, is the St. Lawrence, in Canada, which rising in the lake Affiniboils, passes from one lake to another, from Christineaux to Alempigo; from thence to lake Superior; thence to the lake Hurons; to lake Erie, to lake Ontario; and, at last, after a course of nine hundred leagues, pours their collected waters into the Atlantic Ocean. The river Mississippi is of more than seven hundred leagues, in length, beginning at its source near the lake Affiniboils, and ending at its opening into the gulf of Mexico. The river Plate runs a length of more than eight hundred leagues from its source in the river Parana, to its mouth. The river Oroonoko is seven hundred and fifty-five leagues in length, from its source near Pasto to its discharge into the Atlantic Ocean.

Such is the amazing length of the greatest rivers; and even in some of these, the most remote sources very probably yet continue unknown. In fact, if we consider the number of rivers which they receive, and the little acquaintance we have with the regions through which they run, it is not to be wondered at that geographers are divided concerning the sources of most of them. As among a number of roots by which nourishment is conveyed to a stately tree, it is difficult to determine precisely that by which the tree is chiefly supplied, so among the many branches of a great river, it is equally difficult to tell which is the original. Hence it may easily happen, that a smaller branch is taken for the capital stream; and its runnings are pursued and delineated in prejudice of some other branch that better deserved the name and the description. In this manner in Europe, the Danube is known to receive thirty lesser

ivers: the Wolga, thirty-two or thirty-three. In Asia, the Hohanno receives thirty five; the Jenisca, above sixty; the Oby as many; the Amour about forty; the Nanquin receives thirty rivers; the Ganges twenty; and Euphrates about eleven. In Africa, the Senegal receives more than twenty rivers; the Nile receives not one for five hundred leagues upwards, and then only twelve or thirteen. In America, the river Amazon receives above sixty, and those very considerable; the river St. Lawrence about forty, counting those which fall into its lakes; the Mississippi receives forty; and the river Plate above fifty.

I mentioned the inundations of the Ganges and the Nile, but almost every other great river whose source lies within the tropics have their stated inundations also. The river Pegu has been called by travellers the Indian Nile, because of the similar overflows of its stream; this it does to an extent of thirty leagues on each side; and so fertilizes the soil, that the inhabitants send great quantities of rice into other countries, and have still abundance for their own consumption. The river Senegal has likewise its inundations, which cover the whole flat country of Negroland, beginning and ending much about the same time with those of the Nile; as, in fact, both rivers rise from the same mountains, but the difference between the effects of the inundations in each river is remarkable: in the one, it distributes health and plenty; in the other, diseases, famine, and death. The inhabitants along the torrid coasts of the Senegal can receive no benefit from any additional manure the river may carry down to their soil, which is, by Nature, more than sufficiently luxuriant; or, even if they could, they have not industry to turn it to any advantage. The banks, therefore, of the river lie uncultivated, overgrown with rank and noxious herbage, and infested with thousands of animals of various malignity. Every new flood only tends to increase the rankness of the soil, and to provide fresh shelter for the creatures that infest it. If the flood continues but a few days longer than usual, the improvident inhabitants, who are driven up in the higher grounds, want provisions, and famine ensues. When the river begins to return into its channel, the humidity and heat of the air are equally fatal; and the carcases of infinite numbers of animals, swept away by the inundation, putrifying in the sun, produce a stench that is almost insupportable. But even the luxuriance of the vegetation becomes a nuisance. I have been assured, by persons of veracity who have been up to the river Senegal, that there are some plants growing along the coast, the smell of which is so powerful that it is hardly to be endured. It is certain, that all the sailors and soldiers who have been at any of our factories there ascribe the unwholesomeness of the voyage up the stream to the vegetable vapour. However this may be, the inundations of the rivers in this wretched part of the globe contribute scarce any advantage, if we except the beauty of the prospects which they afford. These, indeed, are finished beyond the utmost reach of art; a spacious glassy river, with its banks here and there fringed to the very surface by the mangrove-tree, that grows down into the water, presents itself to view; lofty forests of various colours, with openings between, carpeted with green plants and the most gaudy flowers; beasts and animals, of various kinds, that stand upon the banks of the river, and, with a sort of wild curiosity, survey the mariners as they pass, contribute to heighten the scene. This is the sketch of an African prospect; which delights the eye even while it destroys the constitution.

Beside these annually periodical inundations, there are many rivers that overflow at much shorter intervals. Thus most of those in Peru and Chili have scarce any motion by night; but upon the appearance of the morning sun they resume their former rapidity: this proceeds from the mountain snows, which, melting with the heat, increase the stream, and continue to drive on the current

while the sun continues to dissolve them. Some rivers also flow with an even steady current, from their source to the sea; others flow with greater rapidity, their stream being poured down in a cataract, or swallowed by the sands, before they reach the sea.

The rivers of those countries that have been least inhabited are usually more rocky, uneven, and broken into waterfalls or cataracts than those where the industry of man has been more prevalent. Wherever man comes Nature puts on a milder appearance: the terrible and the sublime are exchanged for the gentle and the useful; the cataract is sloped away into a placid stream; and the banks become more smooth and even. It must have required ages to render the Rhone or the Loire navigable; their beds must have been cleaned and directed; their inequalities removed; and by a long course of industry, Nature must have been taught to conspire with the desires of her controller. Every one's experience must have supplied instances of rivers thus being made to flow more evenly, and more beneficially to mankind; but there are some whose currents are so rapid and falls so precipitate that no art can obviate, and that must for ever remain as amazing instances of incorrigible Nature.

Of this kind are the cataracts of the Rhine; one of which I have seen exhibit a very strange appearance; it was that at Schathausen, which was frozen quite across, and the water stood in columns where the cataract had formerly fallen. The Nile, as was said, has its cataracts. The river Vologda, in Russia, has two. The river Zara, in Africa, has one near its source. The river Velino, in Italy, has a cataract of above a hundred and fifty feet perpendicular. Near the city of Gottenburgh, in Sweden, the river rushes down from a prodigious high precipice into a deep pit, with such a terrible noise, and dreadful force, that those trees designed for the masts of ships, which are floated down the river, usually are turned upside down in their fall, and often are shattered to pieces, by being dashed against the surface of the water in the pit; this occurs if the masts fall sideways upon the water; but if they fall endways, they dive so far under water, that they disappear for a quarter of an hour or more; the pit into which they are thus plunged has been often sounded with a line of some hundred fathoms long, but no ground has been found hitherto. There is also a cataract at Powerscourt, in Ireland, in which, if I am rightly informed, the water falls three hundred feet perpendicular; which is a greater descent than that of any other cataract in any part of the world. There is a cataract at Albany, in the province of New York, which pours its stream fifty feet perpendicular. But of all the cataracts in the world, that of Niagara, in Canada, if we consider the great body of water that falls, must be allowed to be the greatest and the most astonishing.

This amazing fall of water is made by the river St. Lawrence, in its passage from the lake Erie into the lake Ontario. We have already said the St. Lawrence was one of the largest rivers in the world; and yet the whole of its waters are here poured down, by a fall of a hundred and fifty feet perpendicular. It is not easy to bring the imagination to correspond with the greatness of the scene; a river, extremely deep and rapid, and that serves to drain the waters of almost all North America into the Atlantic Ocean, is here poured precipitately down a ledge of rocks, that rise, like a wall, across the whole bed of its stream. The width of the river a little above is near three quarters of a mile broad; and the rocks, where it grows narrower, are four hundred yards over. Their direction is not straight across, but hollowing inwards like a horse-shoe; so that the cataract, which bends to the shape of the obstacle, rounding inwards, presents a kind of theatre the most tremendous in Nature. Just in the middle of this circular wall of waters, a little island that has braved the fury of the currents presents one of its points, and divides the

stream at top into two; but it unites again long before it has got to the bottom. The noise of the fall is heard at several leagues distance; and the fury of the waters at the bottom of their fall is inconceivable. The dashing produces a mist that rises to the very clouds; and that produces a most beautiful rainbow, when the sun shines. It may easily be conceived, that such a cataract quite destroys the navigation of the stream; and yet some Indian canoes, as it is said, have been known to venture down it with safety.

Of those rivers that lose themselves in the sands, or are swallowed up by chasms in the earth, we have various information. What we are told by the ancients, of the Alpheus, in Aracadia, that sinks into the ground, and rises again near Syracuse, in Sicily, where it takes the name of Arethusa, is rather more known than credited. But we have better information with respect to the river Tigris being lost in this manner under Mount Taurus; of the Guadalquivir, in Spain, being buried in the sands; of the river Greata, in Yorkshire, running under ground, and rising again; and even of the great Rhine itself, a part of which is no doubt lost in the sands a little above Leydon. But it ought to be observed of this river, that by much the greatest part arrives at the ocean; for, although the ancient channel which fell into the sea, a little to the west of that city, is now entirely choked up, yet there are still a number of small canals, that carry a great body of waters to the sea; and, besides, it has also two very large openings, the Lech and the Waal, below Rotterdam, by which it empties itself abundantly.

Be this as it will, nothing is more common in sultry and sandy deserts, than rivers being thus either lost in the sands, or entirely dried up by the sun. And hence we see, that under the line the small rivers are but few; for such little streams as are common in Europe, and which with us receive the name of rivers, would quickly evaporate, in those parching and extensive deserts. It is even confidently asserted, that the great river Niger is thus lost before it reaches the ocean; and that its supposed mouths, the Gambia and the Senegal, are distinct rivers, that come a vast way from the interior parts of the country. It appears, therefore, that the rivers under the line are large; but it is otherwise at the poles, where they must necessarily be small. In that desolate region, as the mountains are covered with perpetual ice, which melts but little, or not at all, the springs and rivulets are furnished with a very small supply. Here, therefore, men and beasts would perish, and die for thirst, if Providence had not ordered that in the hardest winter thaws should intervene, which deposit a small quantity of snow-water in pools under the ice; and from this source the wretched inhabitants drain a scanty beverage.

Thus, whatever quarter of the globe we turn to, we shall find new reasons to be satisfied with that part of it in which we reside. Our rivers furnish all the plenty of the African stream, without its inundation; they have all the coolness of the polar rivulet, with a more constant supply; they may want the terrible magnificence of huge cataracts or extensive lakes, but they are more navigable and more transparent; though less deep and rapid than the rivers of the torrid zone, they are more manageable, and only wait the will of man to take their direction. The rivers of the torrid zone, like the monarchs of the country, rule with despotic tyranny—profuse in their bounties, and ungovernable in their rage. The rivers of Europe, like its kings, are the friends, and not the oppressors, of its people—bounded by no limits, abridged in the power of doing ill, directed by human sagacity, and only at freedom to distribute happiness and plenty.

## CHAP. XV.

### OF THE OCEAN IN GENERAL, AND OF ITS SOFTNESS.

If we look upon a map of the world, we shall find that the ocean occupies considerably more of the globe than the land is found to do. This immense body of waters is diffused round both the old and new continent to the south, and may surround them also to the north for what we know; but the ice in those regions has stopped our inquiries. Although the ocean, properly speaking, is but one extensive sheet of waters continued over every part of the globe without interruption, and although no part of it is divided from the rest, yet geographers have distinguished it by different names, as the Atlantic or Western Ocean, the Northern Ocean, the Southern Ocean, the Pacific Ocean, and the Indian Ocean. Others have divided it differently, and given other names, as the Frozen Ocean, the Inferior Ocean, or the American Ocean. But all these being arbitrary distinctions, and not of Nature's making, the naturalist may consider them with indifference.

In this vast receptacle almost all the rivers of the earth ultimately terminate; nor do such great supplies seem to increase its stores, for it is neither apparently swollen by their tribute, nor diminished by their failure; it still continues the same. Indeed, what is the quantity of water of all the rivers and lakes in the world, compared to that contained in this great receptacle? If we should offer to make a rude estimate, we shall find that all the rivers in the world, flowing into the bed of the sea, with a continuance of their present stores, would take up at least eight hundred years to fill it to its present height. For, supposing the sea to be eighty-five millions of square miles in extent, and a quarter of a mile, upon an average, in depth, this, upon calculation, will give above twenty-one millions of cubic miles of water as the contents of the whole ocean. Now, to estimate the quantity of water which all the rivers supply, take one of them; the Po, for instance, the quantity of whose discharge into the sea, is known to be one cubic mile of water in twenty-six days. Now it will be found, upon a rude computation, from the quantity of ground the Po, with its influent streams, covers, that all the rivers of the world furnish about two thousand times that quantity of water. In the space of a year, therefore, they will have discharged into the sea about twenty-six thousand cubic miles of water; and not till eight hundred years will they have discharged as much water as it contained in the sea at present. I have not troubled the reader with the odd numbers, lest he should imagine I was giving precision to a subject that is incapable of it.

Thus great is the assemblage of waters diffused round our habitable globe; and yet, immeasurable as they seem, they are mostly rendered subservient to the necessities and the conveniences of so little a being as man. Nevertheless, if it should be asked whether they be made for him alone, the question is not easily resolved. Some philosophers have perceived so much analogy to man in the formation of the ocean, that they have not hesitated to assert its being made for him alone. The distribution of land and water, say they, is admirable; the one being laid against the other so skillfully, that there is a just equipoise of the whole globe. Thus the Northern Ocean balances against the Southern; and the new continent is an exact counterweight to the old. As to any objection from the ocean's occupying too large a share of the globe, they contend that there could not have been a smaller surface employed to supply the earth with a due share of evaporation. On the other hand, some take the gloomy side of the question: they either magnify its apparent defects, or assert that what seems defects to us may be real beauties to some wiser order of beings. They observe that multitudes

of animals are concealed in the ocean, and but a small part of them are known; the rest, therefore, they fail not to say, were certainly made for their own benefit, and not for ours. How far either of these opinions be just, I will not presume to determine; but of this we are certain, that God has endowed us with abilities to turn this great extent of waters to our own advantage. He has made these things, perhaps, for other uses; but He has given us faculties to convert them to our own. This much agitated question, therefore, seems to terminate here. We shall never know whether the things of this world have been made for our use; but we very well know that we have been made to enjoy them. Let us, then, boldly affirm that the earth and all its wonders are ours, since we are furnished with powers to force them into our service. Man is the lord of all the sub-lunary creation; the howling savage, the winding serpent, with all the untameable and rebellious offspring of Nature, are destroyed in the contest, or driven at a distance from his habitations. The extensive and tempestuous ocean, instead of limiting or equalising his power, only serves to assist his industry and enlarge the sphere of his enjoyments. Its billows and its monsters, instead of presenting a scene of terror, only call up the courage of this intrepid little being; and the greatest dangers that man now fears on the deep is from his fellow-creatures. Indeed, when I consider the human race as Nature has formed them, there is but little of the habitable globe that seems made for them; but when I consider them as accumulating the experience of ages in commanding the earth, there is nothing so great or so terrible. What a poor contemptible being is the naked savage, standing on the beach of the ocean, and trembling at its tumults! How little capable is he of converting its terrors into benefits, or of saying—Behold an element made wholly for my enjoyment! He considers it as an angry deity, and pays it the homage of submission. But it is far different when he has exercised his mental powers—when he has learned to find his own superiority, and to make it subservient to his command. It is then that his dignity begins to appear, and that the true Deity is justly praised for having been mindful of man—for having given him the earth for his habitation and the sea for an inheritance.

This power which man has obtained over the ocean was at first enjoyed in common; and none pretended to a right in that element where all seemed intruders. The sea, therefore, was open to all till the time of the Emperor Justinian. His successor, Leo, granted such as were in possession of the shore the sole right of fishing before their respective territories. The Thracian Bosphorus was the first that was thus appropriated; and from that time it has been the struggle of most of the powers of Europe to obtain an exclusive right in this element. The republic of Venice claims the Adriatic; the Danes are in possession of the Baltic; but the English have a more extensive claim to the empire of all the seas encompassing England, Scotland, and Ireland; and although these have been long contested, yet they are now considered as their indisputable property. Every one knows that the great power of the nation is exerted on this element, and that the instant England ceases to be superior upon the ocean its safety begins to be precarious.

It is in some measure owing to our dependence upon the sea, and to our commerce there, that we are so well acquainted with its extent and figure. The bays, gulfs, currents, and shallows of the ocean are much better known and examined than the provinces and kingdoms of the earth itself. The hopes of acquiring wealth by commerce has carried man to much greater lengths than the desire of gaining information could have done. In consequence of this, there is scarce a strait or a harbour, scarce a rock or a quicksand, scarce an inflexion of the shore or the jutting of a promontory,

that has not been minutely described. But as these present very little entertainment to the imagination, or delight to any but those whose pursuits are lucrative, they need not be dwelt upon here. While the merchant and the mariner are solicitous in describing currents and soundings, the naturalist is employed in observing wonders, though not so beneficial, yet to him of a much more important nature. The saltiness of the sea seems to be the foremost

Whence the sea has derived that peculiar bitterish saltiness which we find in it, appears by Aristotle to have exercised the curiosity of naturalists in all ages. He supposed (and mankind were for ages content with the solution) that the sun continually raised dry saline exhalations from the earth, and deposited them upon the sea; and hence, say his followers, the waters of the sea are more salt at top than at bottom. But, unfortunately for this opinion, neither of the facts is true. Sea-salt is not to be raised by the vapours of the sun; and sea-water is not saltier at the top than at the bottom. Mr. Bohours is of opinion that the Creator gave the waters of the ocean their saltiness at the beginning, not only to prevent their corruption, but to enable them to bear greater burthens. But their saltiness does not prevent their corruption; for stagnant sea-water, like fresh, soon grows putrid; and, as for their bearing greater burthens, fresh water answers all the purposes of navigation quite as well. The established opinion, therefore, is that a Boyle, who supposes, "That the sea's saltiness is supplied not only from rocks or masses of salt at the bottom of the sea, but also from the salt which the rains and rivers and other waters dissolve in their passage through many parts of the earth, and at length carry with them to the sea." But as there is a difference in the taste of rock-salt found on land and that dissolved in the waters of the ocean, this may be produced by the plenty of nitrous and bituminous bodies that, with the salts, are washed into that great receptacle. These substances, being thus once carried to the sea, must for ever remain there; for they do not rise by evaporation so as to be returned back from whence they came. Nothing but the fresh waters of the sea rise in vapours, and all the saltiness remains behind. From hence it follows that every year the sea must become more and more salt; and this speculation Dr. Halley carries so far, as to lay down a method of finding out the age of the world by the saltiness of its waters. "For if it be observed," says he, "what quantity of salt is at present contained in a certain weight of water, taken up from the Caspian Sea, for example, and, after some centuries, what greater quantity of salt is contained in the same weight of water taken from the same place, we may conclude that, in proportion as the saltiness has increased in a certain time, so much must it have increased before that time; and we may thus, by the rule of proportion, make an estimate of the whole time wherein the water would acquire the degree of saltiness it should then be possessed of." All this may be fine; however, an experiment, begun in this century which is not to be completed till some centuries hence, is rather a little mortifying to modern curiosity; and I am induced to think the inhabitants round the Caspian Sea will not be apt to undertake the inquiry.

This saltiness is found to prevail in every part of the ocean; and as much at the surface as at the bottom. It is also found in all those seas that communicate with the ocean; rather in a less degree.

The great lakes, likewise, that have no outlets nor communication with the ocean, are found to be salt; but some of them in less proportion. On the contrary, all those lakes through which the rivers run into the sea, however extensive they be, are, notwithstanding, very fresh: for the rivers do not deposit their salts in the bed of the lake, but carry them with their currents into the ocean. Thus the lakes Ontario and Erie, in North America, although for magnitude they may be considered

as inland seas, are, nevertheless, fresh-water lakes; and kept so by the river St. Lawrence, which passes through them. But those lakes that have no communication with the sea, nor any rivers going out, although they be less than the former, are, however, always salt. Thus, that which goes by the name of the Dead Sea, though very small when compared to those already mentioned, is so exceedingly salt, that its waters seem scarce capable of dissolving any more. The lakes of Mexico and Titicaca, in Peru, though of no great extent, are, notwithstanding, salt—and both for the same reason.

Those who are willing to turn all things to the best, have not failed to consider this saltiness of the sea as a peculiar blessing from Providence, in order to keep so great an element sweet and wholesome. What foundation there may be in the remark I will not pretend to determine; but we shall shortly find a much better cause for its being kept sweet, namely, its motion.

On the other hand, there have been many who have considered the subject in a different light, and have tried every endeavour to make salt-water fresh, so as to supply the wants of mariners in long voyages, or when exhausted of their ordinary stores. At first it was supposed simple distillation would do; but it was soon found that the bitter part of the water still kept mixed. It was then tried by uniting salt of tartar with sea-water, and distilling both; but here the expense was greater than the advantage. Calcined bones were next thought of; but a hoghead of calcined bones, carried to sea, would take up as much room as a hoghead of water, and was more hard to be obtained. In this state, therefore, have the attempts to sweeten sea-water rested; the chymist satisfied with the reality of his invention; and the mariner convinced of its being useless. I cannot, therefore, avoid mentioning a kind of succedaneum which has been lately conceived to answer the purposes of fresh-water, when mariners are quite exhausted. It is well known that persons who go into a warm bath come out several ounces heavier than they went in; their bodies having imbibed a correspondent quantity of water. This more particularly happens if they have been previously debarred from drinking, or go in with a violent thirst; which they quickly find quenched and their spirits restored. It was supposed, that in case of a total failure of fresh-water at sea, a warm bath might be made of sea-water for the use of mariners; and that their pores would thus imbibe the fluid without any of its salts, which would be seen to crystallize on the surface of their bodies. In this manner, it is supposed, a sufficient quantity of moisture may be procured to sustain life, till time or accident furnish a more copious supply.

But, however this may be, the saltiness of the sea can by no means be considered as a principal cause in preserving its waters from putrefaction. The ocean has its currents, like rivers, which circulate its contents round the globe; and these may be said to be the great agents that keep it sweet and wholesome. Its saltiness alone would by no means answer this purpose: and some have even imagined, that the various substances with which it is mixed rather tend to promote putrescence than impede it. Sir Robert Hawkins, one of our most enlightened navigators, gives the following account of a *cabin*, in which the sea, continuing for some time without motion, began to assume a very formidable appearance. "Were it not," says he "for the moving of the sea, by the force of winds, tides, and currents, it would corrupt all the world! The experiment of this I saw in the year 1590, lying with a fleet about the islands of Azores, almost six months; the greatest part of which time we were becalmed. Upon which all the sea became so replenished with several sorts of jellies, and forms of serpents, adders, and snakes, as seemed wonderful: some green, some black, some yellow, some white, some of diverse colours; and many of them had life; and some there were a yard and a half and two yards long; which,

had I not seen, I could hardly have believed, and hereof are witnesses all the company of the ships which were then present; so that hardly a man could draw a bucket of water clear of some corruption. In which voyage, towards the end thereof, many of every ship fell sick, and began to die apace. But the speedy passage into our country was a remedy to the crazed, and preservative for those that were not touched."

This shows, abundantly, how little the sea's saltiness was capable of preserving it from putrefaction: but to put the matter beyond all doubt, Mr. Boyle kept a quantity of sea-water, taken up in the English Channel, for some time barrelled up, and in the space of a few weeks it began to acquire a foetid smell. He was also assured by one of his acquaintances, who was becalmed for twelve or fourteen days in the Indian Sea, that the water for want of motion began to stink; and that, had it continued much longer, the stench would probably have poisoned him. It is the motion, therefore, and not the saltiness of the sea, that preserves it in its present state of salubrity—and this, most probably, by dashing and breaking in pieces the rudiments, if I may so call them, of the various animals that would otherwise breed there and putrefy.

There are some advantages, however, derived from the saltiness of the sea. Its waters, being evaporated, furnish that salt which is used for domestic purposes; and although in some places it is made from springs, and in others dug out of mines, yet the greatest quantity is made only from the sea. That which is called "bay-salt" (from its coming to us from the Bay of Biscay) is a stronger kind, made from the sun; that called "common-salt" is evaporated in pans over the fire, and is of a much inferior quality to the former.

Another benefit arising from the quantity of salt dissolved in the sea is, that it thus becomes heavier, and consequently more buoyant. Mr. Boyle, who examined the difference between sea-water and fresh, found that the former appeared to be about a forty-fifth part heavier than the latter. Those, also, who have had opportunities of bathing in the sea pretend to have experienced a much greater ease in swimming than in fresh water. However, as we see they have only a forty-fifth part more of their weight sustained by it, I am apt to doubt whether so minute a difference can be practically perceivable. Be this as it may, as sea-water alters in its weight from fresh, so it is found also to differ from itself in different parts of the ocean. In general it is perceived to be heavier, and consequently saltier, the nearer we approach the line.

But there is an advantage arising from the saltiness of the waters of the sea much greater than what has yet been mentioned—which is, that their congelation is thus retarded. Some, indeed, have gone so far as to say that sea-water never freezes; but this is an assertion contradicted by experience. However, it is certain that it requires a much greater degree of cold to freeze it than fresh water; so that, while rivers and springs are seen converted into one solid body of ice, the sea is always fit for navigation; and no way affected by the coldness of the severest winter. It is therefore one of the greatest blessings we derive from this element, that, when on land all the stores of Nature are locked up from us, we find the sea ever open to our necessities, and patient of the hand of industry.

But it must not be supposed that because in our temperate climates we never see the sea frozen it is in the same manner open in every part of it; a very little acquaintance with the accounts of mariners must have informed us, that at the polar regions it is embarrassed with mountains and moving sheets of ice that often render it impassable. These tremendous floats are of different magnitudes—sometimes rising more than a thousand feet above the surface of the water, sometimes diffused into plains of above two hundred leagues in

length, and in many parts sixty or eighty broad. They are usually divided by fissures, one piece following another so close that a person may step from one to the other. Sometimes mountains are seen rising amidst these plains, and presenting the appearance of a variegated landscape, with hills and valleys, houses, churches, and towers. These are appearances in which all naturalists are agreed; but the great contest is respecting their formation. Mr. Buffon asserts that they are formed from fresh water alone, which, congealing at the mouths of great rivers, accumulate those huge masses that disturb navigation. However, this great naturalist seems not to have been aware that there are two sorts of ice floating in these seas—the flat ice and the mountain ice; the one formed of sea-water only—the other of fresh.

The flat or driving ice is entirely composed of sea-water, which upon dissolution is found to be salt, and is readily distinguished from the mountain or fresh-water ice by its whiteness and want of transparency. This ice is much more terrible to mariners than that which rises up in lumps: a ship can avoid the one, as it is seen at a distance; but often gets in among the other, which, sometimes closing, crushes it to pieces. This, which manifestly has a different origin from the fresh-water ice, may perhaps have been produced from the Icy Sea, beneath the pole; or along the coasts of Spitzbergen or Nova Zembla.

The mountain ice, as was said, is different in every respect, being formed of fresh water, and appearing hard and transparent; it is generally of a pale-green colour, though some are of a beautiful sky blue; many large masses also appear grey, and some black. If examined more closely, they are found to be incorporated with earth, stones, and brushwood washed from the shore. On these, also, are sometimes found not only earth, but nests with birds' eggs, at several hundred miles from land. The generality of these, though almost totally fresh, have a thick crust of salt water frozen upon them, probably from the power that ice has sometimes to produce ice. Such mountains as are here described are most usually found at spring-time, and after a violent storm, driving out to sea, where they at first terrify the mariner, and are soon after dashed to pieces by the continual washing of the waves, or driven into the warmer regions of the south, there to be melted away. They sometimes, however, strike back upon their native shores, where they seem to take root at the feet of the mountains, and (as Martius tells us) are sometimes higher than the mountains themselves. Those seen by him were blue, full of clefts and cavities made by the rain, and crowned with snow, which, alternately thawing and freezing every year, augmented their size. These, composed of materials more solid than that driving at sea, presented a variety of agreeable figures to the eye that, with a little help from fancy, assumed the appearance of trees in blossom; the inside of churches, with arches, pillars, and windows, and the blue-coloured rays darting from within, presented the resemblance of a gloria.

If we inquire into the origin and formation of these—which, as we see, are very different from the former—I think we have a very satisfactory account in the following passage from Crantz:—"These mountains of ice," he says, "are not salt, like sea water, but sweet; and therefore can be formed nowhere except on the mountains, in rivers, in caverns, and against the hills near the sea-shore. The mountains of Greenland are so high, that the snow which falls upon them, particularly on the north side, is in one night's time wholly converted into ice. They also contain clefts and cavities where the sun seldom or never injects his rays. Besides these are projections, or landing-places, on the declivities of the steepest hills, where the rain and snow-water lodge and quickly congeal. When the accumulated flakes of snow slide down, or fall with the rain from the eminences above on these prominences; or, when here and

there a mountain spring comes rolling down to such a lodging-place where the ice has already seated itself, they all freeze, and add their tribute to it. This, by degrees, waxes to a body of ice that can no more be overpowered by the sun, and which, though it may at certain seasons diminish by a thaw, yet upon the whole, through annual acquisitions, it assumes an annual growth. Such a body of ice is often prominent far over the rocks. It does not melt on the upper surface, but underneath, and often cracks into many larger or smaller clefts, from whence the thawed water trickles out. By this it becomes at last so weak, that, being overloaded with its own ponderous bulk, it breaks loose, and tumbles down the rocks with a terrible crash. Where it happens to overhang a precipice on the shore, it plunges into the deep with a shock like thunder, and with such an agitation of the water as will overturn a boat at some distance, as many a poor Greenlander has fatally experienced." Thus are these amazing ice-mountains launched forth to sea, and found floating in the waters round both the poles. It is these that have hindered mariners from discovering the extensive countries which lie round the South Pole, and which probably block up the passage to China by the north.

I will conclude this chapter with one effect more produced by the saltness of the sea, which is the luminous appearance of its waves in the night. All who have been spectators of a sea by night a little ruffled by winds, seldom fail of observing its fiery brightness. In some places it shines as far as the eye can reach; at other times, only when the waves boom against the side of the vessel, or the oar dashes into the water. Some seas shine often—others more seldom; some, ever when particular winds blow—others within a narrow compass; a long tract of land being seen along the surface, whilst all the rest is hid in total darkness. It is not easy to account for these extraordinary appearances; some have supposed that a number of luminous insects produced the effect—and this is really sometimes the case; in general, however, they have every resemblance to that light produced by electricity, and probably arise from the agitation and dashing of the saline particles of the fluid against each other. But the manner in which this is done—for we can produce nothing similar by any experiments hitherto made—remains for some happier accident to discover. Our progress in the knowledge of Nature is slow; and it is a mortifying consideration, that we are, hitherto, more indebted for success to chance than industry.

## CHAP. XVI.

### OF THE TIDES, MOTION, AND CURRENTS OF THE SEA, WITH THEIR EFFECTS.

It was said in the former chapter that the waters of the sea were kept sweet by their motion, without which they would soon putrefy and spread universal infection. If we look for final causes, here indeed we have a great and an obvious one that presents itself before us. Had the sea been made without motion, and resembling a pool of stagnant water, the nobler races of Animated Nature would shortly be at an end. Nothing would then be left alive but swarms of ill-formed creatures, with scarce more than vegetable life, and subsisting by putrefaction. Were this extensive bed of waters entirely quiescent, millions of the smaller reptile kinds would there find a proper retreat to breed and multiply in; they would find there no agitation—no concussion in the parts of the fluid to crush their feeble frames, or to force them from the places where they were bred; there they would multiply in security and ease, enjoy a short life, and putrefying, thus again give nourishment to

numberless others as little worthy of existence as themselves. But the motion of this great element effectually destroys the number of these viler creatures; its currents and its tides produce continual agitations, the shock of which they are not able to endure; the parts of the fluid rubbing against each other destroy all viscidities; and the ocean, if I may so express it, acquires health by exercise.

The most obvious motion of the sea, and the most generally acknowledged, is that of its tides. The element is observed to flow for certain hours, from south towards the north; in which motion or flux, which lasts about six hours, the sea gradually swells; so that entering the mouths of rivers, it drives back the river-waters to their heads. After a continual flux of six hours, the sea seems to rest for a quarter of an hour; and then begins to ebb, or retire back again, from north to south for six hours more; in which time the waters sinking, the rivers resume their natural course. After a seeming pause of a quarter of an hour, the sea again begins to flow as before: and thus it has alternately risen and fallen, twice a-day, since the creation.

This amazing appearance did not fail to excite the curiosity as it did the wonder of the ancients. After some wild conjectures of the earliest philosophers, it became well known in the time of Pliny that the tides were entirely under the influence, in a small degree, of the sun; but in a greater of the moon. It was found that there was a flux and reflux of the sea in the space of twelve hours fifty minutes, which is exactly the time of a lunar day. It was observed that, whenever the moon was in the meridian, or, in other words, as nearly as possible over any part of the sea, that the sea flowed to that part and made a tide there; on the contrary, it was found that when the moon left the meridian the sea began to flow back again from whence it came, and there might be said to ebb. Thus far the waters of the sea seemed regularly to attend the motions of the moon. But as it appeared, likewise, that when the moon was in the opposite meridian as far off on the other side of the globe, there was a tide on this side also; so that the moon produced two tides—one by her greatest approach to us, and another by her greatest distance from us; in other words, the moon, in once going round the earth, produced two tides at the same time—one on the other part of the globe directly under her, and the other on the part of the globe directly opposite.

Mankind continued for several ages content with knowing the general cause of these wonders, hopeless of discovering the particular manner of the moon's operation. Kelper was the first who conjectured that attraction was the principal cause, asserting that the sphere of the moon's operation extended to the earth, and drew up its waters. The precise manner in which this is done was discovered by Newton.

The moon has been found, like all the rest of the planets, to attract and to be attracted by the earth. This attraction prevails throughout our whole planetary system. The more matter there is contained in any body, the more it attracts; and its influence decreases in proportion as the distance, when squared, increases. This being premised, let us see what must ensue upon supposing the moon in the meridian of any tract of the sea. The surface of the water immediately under the moon is nearer the moon than any other part of the globe is; and, therefore, must be more subject to its attraction than the waters any where else. The waters will, therefore, be attracted by the moon, and rise in a heap; whose eminence will be the highest where the attraction is greatest. In order to form this eminence, it is obvious that the surface, as well as the depths, will be agitated; that wherever the water runs from one part, succeeding waters must run to fill up the space it has left. Thus the waters of the sea, running from all parts to attend the motions of the moon, produce the flowing

of the tide; and it is high tide at that part wherever the moon comes over it, or to its meridian.

But when the moon travels onward, and ceases to point over the place where the waters were just risen, the cause here of their rising ceasing to operate, they will flow back by their natural gravity into the lower parts from whence they had travelled; and this retiring of the waters will form the ebbing of the sea.

Thus the first part of the demonstration is obvious; since, in general, it requires no great sagacity to conceive that the waters nearest the moon are most attracted, or raised highest by the moon. But the other part of the demonstration, namely, how there come to be high tides at the same time, on the opposite side of the globe, and where the waters are farthest from the moon, is not so easy to conceive. To comprehend this, it must be observed, that the part of the earth and its waters that are farthest from the moon are the parts of all others that are least attracted by the moon: it must be observed, that all the waters, when the moon is on the opposite side of the earth, must be attracted by it in the same direction that the earth itself attracts them; that is, if I may so say, quite through the body of the earth, towards the moon itself. This, therefore, being conceived, it is plain that those waters which are furthest from the moon will have less weight than those of any other part on the same side of the globe; because the moon's attraction, which conspires with the earth's attraction, is there least. Now, therefore, the waters farthest from the moon, having less weight, and being lightest, will be pressed on all sides by those that, having more attraction, are heavier: they will be pressed, I say, on all sides; and the heavier waters flowing in will make them swell and rise in an eminence directly opposite to that on the other side of the globe, caused by the more immediate influence of the moon.

In this manner, the moon, in one diurnal revolution, produces two tides; one raised immediately under the sphere of its influence, and the other directly opposite to it. As the moon travels, this vast body of waters rears upward, as if to watch its motions; and pursues the same constant rotation. However, in this great work of raising the tides the sun has no small share; it produces its own tides constantly every day, just as the moon does, but in a much less degree, because the sun is at an immensely greater distance. Thus there are solar tides. When the forces of these two great luminaries concur, which they always do when they are either in the same or in opposite parts of the heavens, they jointly produce a much greater tide than when they are so situated in the heavens as each to make peculiar tides of their own. To express the very same thing technically; in the conjunctions and oppositions of the sun and moon, the attraction of the sun conspires with the attraction of the moon—by which means the high spring-tides are formed. But in the quadratures of the sun and moon, the water raised by the one is depressed by the other; and hence the lower neap-tides have their production. In a word, the tides are greatest in the syzgies, and least in the quadratures.

This theory well understood, and the astronomical terms previously known, it may readily be brought to explain the various appearances of the tides, if the earth were covered with a deep sea, and the waters uninfluenced by shoals, currents, straits, or tempests. But in every part of the sea, near the shores, the geographer must come in to correct the calculations of the astronomer. For, by reason of the shallowness of some places and the narrowness of the straits in others, there arises a great diversity in the effect, not to be accounted for without an exact knowledge of all the circumstances of the place. In the great depths of the ocean, for instance, a very slow and imperceptible motion of the whole body of water will suffice to raise its surface several feet high; but if the same increase of water is to

be conveyed through a narrow channel, it must rush through it with the most impetuous rapidity. Thus, in the English Channel, and the German Ocean, the tide is found to flow strongest in those places that are narrowest; the same quantity of water being, in this case, driven through a smaller passage. It is often seen, therefore, pouring through a strait with great force; and by its rapidity considerably raised above the surface of that part of the ocean into which it runs.

This shallowness and narrowness in many parts of the sea also give rise to a peculiarity in the tides of some parts of the world. For in many places, and in our own seas in particular, the greatest swell of the tide is not while the moon is in its meridian height, and directly over the place, but some time after it has declined from thence. The sea, in this case, being obstructed, pursues the moon with what despatch it can, but does not arrive with all its waters till long after the moon has ceased to operate. Lastly, from this shallowness of the sea, and from its being obstructed by shoals and straits, we may account for the Mediterranean, the Baltic, and the Black Sea having no sensible tides. These, though to us they seem very extensive, are not, however, large enough to be affected by the influence of the moon; and as to their communication with the ocean through such narrow inlets, it is impossible in a few hours time that they should receive and return water enough to raise or depress them in any considerable degree.

In general, therefore, we may observe, that all tides are much higher and more considerable in the torrid zone than in the rest of the ocean; the sea in those parts being generally deeper and less affected by changeable winds or winding shores. The greatest tide we know of is that at the mouth of the river Indus, where the water rises thirty feet in height. How great, therefore, must have been the amazement of Alexander's soldiers at so strange an appearance! They who always before had been accustomed only to the scarcely perceptible risings of the Mediterranean, or the minute intumescence of the Black Sea, when made at once spectators of a river rising and falling thirty feet in a few hours, must no doubt have felt the most extreme awe, with a mixture of curiosity and apprehension. The tides are also remarkably high on the coasts of Malay, in the straits of Sunday, in the Red Sea, at the mouth of the river St. Lawrence, along the coasts of China and Japan, at Panama, and in the gulf of Bengal. The tides at Tonquin, however, are the most remarkable in the world. In this part there is but one tide and one ebb in twenty-four hours; whereas, as we have said before, in other places there are two. Besides, twice in each month, when the moon is near the equinoctial, there is no tide at all—the water being for some time quite stagnant. These, with some other odd appearances attending the same phenomena, were considered by many as inscrutable; but Sir Isaac Newton, with peculiar sagacity, adjudged them to arise from the concurrence of two tides—one from the South Sea, and the other from the Indian Ocean. Of each of these tides there come successively two every day—two at one time greater, and two at another that are less. The time between the arrival of the two greater is considered by him as high tide—the time between the two lesser as ebb. In short, with this clue that great mathematician solved every appearance, and so established his theory as to silence every opposer.

This fluctuation of the sea from the tides produces another and more constant rotation of its waters from the east to the west—in this respect following the course of the moon. This may be considered as one great and general current of the waters of the sea; and although it be not every where distinguishable, it is nevertheless every where existent, except when opposed by some particular current or eddy produced by partial and local

causes. This tendency of the sea towards the west is plainly perceivable in all the great straits of the ocean—as, for instance, in those of Magellan, where the tide, running in from the east, rises twenty feet high, and continues flowing six hours; whereas the ebb continues but two hours, and the current is directed to the west. This proves that the flux is not equal to the reflux; and that from both results a motion of the sea westward, which is more powerful during the time of the flux than the reflux.

But this motion westward has been sensibly observed by navigators in their passage back from India to Madagascar, and so on to Africa. In the great Pacific Ocean, also, it is very perceivable; but the places where it is most obvious are, as was said, in those straits which join one ocean to another—in the straits between the Maldiva Islands, in the gulf of Mexico, between Cuba and Yucatan. In the straits of the gulf of Paria, the motion is so violent that it has received the appellation of the Dragon's Mouth. Northward, in the sea of Canda, in Waigat's Straits, in the straits of Java, and, in short, in every strait where the ocean on one part pours into the ocean on the other. In this manner, therefore, is the sea carried with an unceasing circulation round the globe; and, at the same time that its waters are pushed backward and forward with the tide, they have thus a progressive current to the west, which, though less observable, is not the less real.

Besides these two general motions of the sea, there are others which are particular to many parts of it, and are called "currents." These are found to run in all directions—east, west, north, and south—being formed, as was said above, by various causes; the prominence of the shores, the narrowness of the straits, the variations of the wind, and the inequalities at the bottom. These—though no great object to the philosopher, as their causes are generally local and obvious—are of the most material consequence to the mariner, and without a knowledge of which he could never succeed. It often has happened, that when a ship has unknowingly got into one of these everything seems to go forward with success; the mariners suppose themselves every hour approaching their wished-for port—the wind fills their sails—and the ship's prow seems to divide the water; but at last, by miserable experience, they find that instead of going forward they have been all the time receding. The business of currents, therefore, makes a considerable article in navigation; and the direction of their stream and their rapidity has been carefully set down. This some do by the observation of the surface of the current, or by the driving of the froth along the shore, or by throwing out the log-line, with a buoy made for that purpose, and by the direction and motion of this they judge of the setting and rapidity of the current.

These currents are generally found to be most violent under the equator, where indeed all the motions of the ocean are most perceivable. Along the coast of Guinea, if a ship happens to overshoot the mouth of any river it is bound to, the current prevents its return; so that it is obliged to steer out to sea, and take a very large compass, in order to correct the former mistake. These set in a contrary direction to the general motion of the sea westward—and that so strongly, that a passage which, with the current, is made in two days, is with difficulty performed in six weeks against it. However, they do not extend above twenty leagues from the coast; and ships going to the East Indies take care not to come within the sphere of their action. At Sumatra, the currents, which are extremely rapid, run from south to north: there are also strong currents between Madagascar and the Cape of Good Hope. On the western coasts of America the current always runs from the south to the north, where a south wind continually blowing most probably occasions this phenomenon. But the currents that are most remarkable are those

continually flowing in the Mediterranean Sea, both from the ocean by the straits of Gibraltar and its other extremity from the Euxine Sea by the Archipelago. This is one of the most extraordinary appearances in Nature, this large sea receiving not only the numerous rivers that fall into it—such as the Nile, the Rhone, and the Po—but also a very great influx from the Euxine Sea on one part and the ocean on the other. At the same time, it is seen to return none of the waters it is thus known to receive. Outlets running from it there are none; no rivers but such as bring it fresh supplies; no straits but what are constantly pouring their waters into it. It has therefore been the wonder of mankind in every age how and by what means this vast concourse of waters are disposed of; or how this sea, which is always receiving and never returning, is no way fuller than before. In order to account for this, some have said that the water was re-conveyed by subterraneous passages into the Red Sea. There is a story told of an Arabian califf who caught a dolphin in this sea, admiring the beauty of which he let it go again, having previously marked it by a ring of iron. Some time after a dolphin was caught in the Red Sea, and quickly known by the ring to be the same that had been taken in the Mediterranean before. Such, however, as have not been willing to found their opinions upon a story, have endeavoured to account for the disposal of the waters of the Mediterranean by evaporation. For this purpose they have entered into long calculations upon the extent of its surface, and the quantity of water that would be raised from such a surface in a year. They then compute how much water runs in by its rivers and straits in that time, and find that the quantity exhausted by evaporation greatly exceeds the quantity supplied by rivers and seas. This solution no doubt would be satisfactory did not the ocean and the Euxine evaporate as well as the Mediterranean; and as these are subject to the same drain, it must follow that all the seas will in this respect be upon a par; and therefore there must be some cause for this unperceived drain and continual supply. This seems to be satisfactorily accounted for by Dr. Smith, who supposes an under current running through the straits of Gibraltar to carry out as much water into the ocean as the upper current continually carries in from it. To confirm this, he observes that nearer home, between the north and the south foreland, the tide is known to run one way and the ebb another way at bottom. This double current he also confirms by an experiment communicated to him by an able seaman, who, being with one of the king's frigates in the Baltic, found he went with his boat into the mid-stream, and was carried violently by the current; upon which a basket was sunk, with a large cannon-ball, to a certain depth of water, which gave a check to the boat's motion; as the basket sunk still lower, the boat was driven, by the force of the water below, against the upper current; and the lower the basket was let down the stronger the under current was found, and the quicker was the boat's motion against the upper stream, which seemed not to be above four fathoms deep. From hence we may readily infer that the same cause may operate at the straits of Gibraltar; and that while the Mediterranean seems replenishing at top it may be empty at bottom.

The number of the currents at sea are impossible to be recounted, nor indeed are they always known; new ones are daily produced by a variety of causes, and as quickly disappear. When a regular current is opposed by another in a narrow strait, or where the bottom of the sea is very uneven, a whirlpool is often formed. These were formerly considered as the most formidable obstructions to navigation; and the ancient poets and historians speak of them with terror; they are described as swallowing up ships, and dashing them against the rocks at the bottom; apprehension did not fail to add imaginary terrors to the description—placing at the cen-

tre of the whirlpool a dreadful den, fraught with monsters whose howlings served to add new horrors to the dashings of the deep. Mankind at present, however, view the eddies of the sea with very little apprehension; and some have wondered how the ancients could have so much overcharged their descriptions. But all this is very naturally accounted for. In those times when navigation was in its infancy, and the slightest concussion of the waves generally sent the poor adventurer to the bottom, it is not to be wondered at that he was terrified at the violent agitations in one of these. When his little ship, but ill fitted for opposing the fury of the sea, was got within the vortex, there was then no possibility of ever returning. To add to the fatality, they were always near the shore; and along the shore was the only place where this ill-provided mariner durst venture to sail. These were, therefore, dreadful impediments to his navigation; for if he attempted to pass between them and the shore, he was sometimes sucked in by the eddy; and if he attempted to avoid them out at sea, he was often sunk by the storm. But in our time, and in our present improved state of navigation, Charybdis and the Euripus, with all the other irregular currents of the Mediterranean, are no longer formidable. Mr. Addison not attending to this train of thinking, upon passing through the straits of Sicily, was surprised at the little there was of terror in the present appearance of Sylla and Charybdis; and seems to be of opinion that their agitations are much diminished since the times of antiquity. In fact, from the reasons above, all the wonders of the Mediterranean Sea are described in much higher colours than they merit, to us who are acquainted with the more magnificent terrors of the ocean. The Mediterranean is one of the smoothest and most gentle seas in the world: its tides are scarce perceptible, except in the Gulf of Venice, and shipwrecks are less known there than in any other part of the world.

It is in the ocean, therefore, that these whirlpools are particularly dangerous, where the tides are violent and the tempests fierce. To mention only one, that called the Maelstrom, upon the coast of Norway, which is considered as the most dreadful and voracious in the world. The name it has received from the natives signifies "the navel of the sea"—since they suppose that a great share of the water of the sea is sucked up and discharged by its vortex. A minute description of the internal parts is not to be expected, since none who were there ever returned to bring back information. The body of the waters that form this whirlpool are extended in a circle above thirteen miles in circumference. In the midst of this stands a rock, against which the tide in its ebb is dashed with inconceivable fury. At this time it instantly swallows up all things that come within the sphere of its violence—trees, timber, and shipping. No skill in the mariner nor strength of rowing can work an escape; the sailor at the helm finds the ship at first goes in a current opposite to his intentions; his vessel's motion, though slow in the beginning, becomes every moment more rapid; it grows round in circles still narrower and narrower, till at last it is dashed against the rocks, and instantly disappears: nor is it seen again for six hours; till, the tide flowing, it is vomited forth with the same violence with which it was drawn in. The noise of this dreadful vortex still farther contributes to increase its terror, which, with the dashing of the waters, and the dreadful valley, if it may be so called, caused by their circulation, makes one of the most tremendous objects in Nature.

## CHAP. XVII

## OF THE CHANGES PRODUCED BY THE SEA UPON THE EARTH.

From what has been said, as well of the earth as of the sea, they both appear to be in continual fluctuation. The earth—the common promptuary that supplies subsistence to men, animals, and vegetables—is continually furnishing its stores to their support. But the matter which is thus derived from it is soon restored and laid down again to be prepared for fresh mutations. The transmigration of souls is no doubt false and whimsical; but nothing can be more certain than the transmigration of bodies. The spoils of the meanest reptile may go to the formation of a prince; and, on the contrary, as the poet has it, the body of Cæsar may be employed in stopping a beer-barrel. From this and other causes, therefore, the earth is in continual change. Its internal fires, the deviation of its rivers, and the falling of its mountains, are daily altering its surface; and geography can scarce recollect the lakes and the valleys that history once described.

But these changes are nothing to the instability of the ocean. It would seem that inquietude was as natural to it as its fluidity. It is first seen with a constant and equable motion going towards the west; the tides then interrupt this progression, and for a time drive the waters in a contrary direction. Besides these agitations, the currents act their part in a smaller sphere, being generally greatest where the other motions of the sea are least—namely, nearest the shore; the winds also contribute their share in this universal fluctuation; so that scarce any part of the sea is wholly seen to stagnate.

As this great element is thus changed, and continually labouring internally, it may be readily supposed that it produces correspondent changes upon its shores and those parts of the earth subject to its influence. In fact, it is every day making considerable alterations, either by overflowing its shores in one place or deserting them in others; by covering over whole tracts of country that were cultivated and peopled at one time, or by leaving its bed to be appropriated to the purposes of vegetation, and to supply a new theatre for human industry at another.

In this struggle between the earth and the sea for dominion, the greatest number of our shores seem to defy the whole rage of the waves, both by their height and the rocky materials of which they are composed. The coasts of Italy, for instance, are bordered with rocks of marble of different kinds, the quarries of which may easily be distinguished at a distance from sea, and appear like perpendicular columns of the most beautiful kinds of marble, ranged along the shore. In general, the coasts of France, from Brest to Bordeaux, are composed of rocks; as are also those of Spain and England, which defend the land, and are only interrupted here and there to give an egress to rivers, and to grant the convenience of bays and harbours to our shipping. It may be in general remarked, that wherever the sea is most violent and furious there the boldest shores, and of the most compact materials, are found to oppose it. There are many shores several hundred feet perpendicular, against which the sea, when swollen with tides or storms, rises and beats with inconceivable fury. In the Orkneys, where the shores are thus formed, it sometimes when agitated by a storm rises two hundred feet perpendicular, and dashes up its spray, together with sand and other substances that compose its bottom, upon land like showers of rain.

From hence, therefore, we may conceive how the violence of the sea and the boldness of the shore may be said to have made each other. Where the sea meets no obstacles it spreads its waters with a gentle intumescence, till all its power is destroyed by wanting depth

to aid the motion. But when its progress is checked in the midst by the prominence of rocks or the abrupt elevation of the land, it dashes with all the force of its depth against the obstacle, and forms, by its repeated violence, that abruptness of the shore which confines its impetuosity. Where the sea is extremely deep or much vexed by tempests, it is no small obstacle that can confine its rage; and for this reason we see the boldest shores projected against the deepest waters—all less impediments having long before been surmounted and washed away. Perhaps of all the shores in the world there is not one so high as that on the west of St. Kilda, which upon admeasurement was found to be 600 fathoms perpendicular above the surface of the sea. Here the sea is deep, turbulent, and stormy; so that it requires great force in the shore to oppose its violence. In many parts of the world, and particularly upon the coasts of the East Indies, the shores, though not high above water, are generally very deep, and consequently the waves roll against the land with great weight and irregularity. This rising of the waves against the shores is called by mariners "the surf of the sea," and in shipwrecks is generally fatal to such as attempt to swim on shore. In this case no dexterity in the swimmer, no float he can use, neither swimming-girdle nor cork-jacket, will save him; the weight of the superincumbent waves break upon him at once, and crushes him with certain ruin. Some few of the natives, however, have the art of swimming and navigating their little boats near those shores where an European is sure of instant destruction.

In places where the force of the sea is less violent, or its tides less rapid, the shores are generally seen to descend with a more gradual declivity. Over these, the waters of the tide steal by almost imperceptible degrees, covering them for a large extent, and leaving them bare on its recess. Upon these shores, as was said, the sea seldom beats with any great violence, as a large wave has not depth sufficient to float it onwards—so that here only are to be seen gentle surges making calmly towards land, and lessening as they approach. As the sea, in the former description, is generally seen to present prospects of tumult and uproar, here it more usually exhibits a scene of repose and tranquil beauty. Its waters—which, when surveyed from the precipice, afforded a muddy greenish hue, arising from their depth and position to the eye—when regarded from the shelving shore wear the colour of the sky, and seem rising to meet it. The deafening noise of the sea is here converted into gentle murmurs; instead of the water dashing against the face of the rock, it advances and recedes, still going forward, but with just force enough to push its weeds and shells by insensible approaches to the shore.

There are other shores, besides those already described, which either have been raised by Art to oppose the sea's approaches, or, from the sea's gaining ground, are threatened with imminent destruction. The sea's being thus seen to give and take away lands at pleasure, is without question one of the most extraordinary considerations in all natural history. In some places it is seen to obtain the superiority by slow and certain approaches, or to burst in at once, and overwhelm all things in undistinguished destruction; in other places it departs from its shores, and where its waters have been known to rage, it leaves fields covered with the most beautiful verdure.

The formation of new lands by the sea's continually bringing its sediment to one place, and by the accumulation of its sands in another, is easily conceived. We have had many instances of the in England. The island of Oxney, which is adjacent to Romney-marsh, was produced in this manner. This had for a long time been a low level, continually in danger of being overflowed by the river Rother; but the sea, by its depositions, has

gradually raised the bottom of the river, while it has hollowed the mouth; so that the one is sufficiently secured from inundations, and the other is deep enough to admit ships of considerable burden. The like also may be seen at that bank called the "Dogger sands," where two tides meet, and which thus receive new increase every day—so that in time the place seems to promise fair for being habitable earth. On many parts of the coasts of France, England, Holland, Germany, and Prussia, the sea has been sensibly known to retire. Hubert Thomas asserts, in his Description of the Country of Liege, that the sea formerly encompassed the city of Tongres, which, however, is at present thirty-five leagues distant from it. This assertion he supports by many strong reasons; and among others, by the iron rings fixed in the walls of the town, for fastening the ships that came into the port. In Italy there is a considerable piece of ground, gained at the mouth of the river Arno; and Ravenna, that once stood by the sea-side, is now considerably removed from it. But we need scarce mention these, when we find that the whole republic of Holland seems to be a conquest upon the sea, and, in a manner, rescued from its bosom. The surface of the earth in this country is below the level of the bed of the sea; and I remember, upon approaching the coast, to have looked down upon it from the sea as into a valley; however, it is every day rising higher by the depositions made upon it by the sea, the Rhine, and the Meuse; and those parts which formerly admitted large men-of-war are now known to be too shallow to receive ships of very moderate burthen. The province of Yucatan, a peninsula in the Gulf of Mexico, was formerly a part of the sea. This tract, which stretches out into the ocean a hundred leagues, and which is above thirty leagues broad, is everywhere, at a moderate depth below the surface, composed of shells, which evince that its land once formed the bed of the sea. In France, the town of Aigues Mortes was a port in the time of St. Louis, which is now removed more than four miles from the sea. Palmodi, in the same kingdom, was an island in the year 815, but is now more than six miles from the shore. All along the coasts of Norfolk, I am well assured, that in the memory of man the sea has gained fifty yards in some places, and lost as much in others.

Thus numerous, therefore, are the instances of new lands having been produced from the sea, which, as we see, is brought about two different ways—first, by the waters raising banks of sand and mud where their sediment is deposited; and, secondly, by their relinquishing the shore entirely, and leaving it unoccupied to the industry of man.

But as the sea has been thus known to recede from some lands, so has it, by fatal experience, been found to encroach upon others; and probably these depredations on one part of the shore may account for their dereliction from another; for the current which rested upon some certain bank, having got an egress in some other place, it no longer presses upon its former bed, but pours all its stream into the new entrance; so that every inundation of the sea may be attended with some correspondent dereliction of another shore.

However this be, we have numerous histories of the sea's inundations, and of its burying whole provinces in its bosom. Many countries that have been thus destroyed bear melancholy witness to the truth of history, and show the tops of their houses and the spires of their steeples still standing at the bottom of the water. One of the most considerable inundations we have in history is that which happened in the reign of Henry I., which overflowed the estates of the Earl Godwin, and now forms that bank called the Goodwin Sands. In the year 1546 a similar eruption of the sea destroyed a hundred thousand persons in the territory of Dordt, and yet a greater number round Dullart. In Friesland and

Zealand there were more than three hundred villages overwhelmed; and their ruins continue still visible at the bottom of the water in a clear day. The Baltic Sea has, by slow degrees, covered a large part of Pomerania; and, among others, destroyed and overwhelmed the famous port of Vineta. In the same manner, the Norwegian Sea has formed several little islands from the main land, and still daily advances upon the continent. The German Sea has advanced upon the shores of Holland, near Catt; so that the ruins of an ancient citadel of the Romans, which was formerly built upon this coast, are now actually under water. To these accidents several more might be added; our own historians and those of other countries abound with them—almost every flat shore of any extent being able to show something it has lost or something it has gained from the sea.

There are some shores on which the sea has made temporary depredations—where it has overflowed, and, after remaining perhaps some ages, it has again retired of its own accord, or been driven back by the industry of man. There are many lands in Norway, Scotland, and the Maldivia Islands that are at one time covered with water and at another free. The country round the Isle of Ely, in the time of Bede (about 1100 years ago), was one of the most delightful spots in the whole kingdom; it was not only richly cultivated, and produced all the necessaries of life, but grapes also that afforded excellent wine. The accounts of that time are copious in the description of its verdure and fertility—its rich pastures covered with flowers and herbage—its beautiful shades and open air. But the sea, breaking in upon the land, overwhelmed the whole country, took possession of the soil, and totally destroyed one of the most fertile valleys in the world. Its air, from being dry and healthful, from that time became most unwholesome and clogged with vapours; and the small part of the country that, by being higher than the rest, escaped the deluge, was soon rendered uninhabitable from its noxious vapours. Thus this country continued under water for some centuries; till at last the sea, by the same caprice which had prompted its invasions, began to abandon the earth in like manner. It has continued for some ages to relinquish its former conquests; and although the inhabitants can neither boast the longevity nor the luxuries of their former pre-occupants, yet they find ample means of subsistence; and if they happen to survive the first years of their residence there, they are often known to arrive at a good old age.

But although history be silent as to many other inundations of the like kind, where the sea has overflowed the country and afterwards retired, yet we have numberless testimonies of another nature that prove it beyond the possibility of doubt. I mean those numerous trees that are found buried at considerable depths in places where either rivers or the sea has accidentally overflowed. At the mouth of the river Nees, near Bruges, in Flanders, at the depth of fifty feet, are found great quantities of trees lying as close to each other as they do in a wood; the trunks, the branches, and the leaves are in such perfect preservation, that the particular kind of each tree may instantly be known. About five hundred years ago this very ground was known to have been covered with the sea; nor is there any history or tradition of its having been dry ground, which we can have no doubt must have been the case. Thus we see a country flourishing in verdure, producing large forests, and trees of various kinds, overwhelmed by the sea. We see this element depositing its sediment to a height of fifty feet; and its waters must, therefore, have risen much higher. We see the same, after it has thus overwhelmed and sunk the land so deep beneath its slime, capriciously retiring from the same coasts, and leaving that habitable once more which it had formerly destroyed. All this is wonderful; and perhaps, instead of attempting to inquire

after the cause, which has hitherto been inscrutable, it will best become us to rest satisfied with admiration.

At the city of Modena, in Italy, and about four miles round it, wherever it is dug, when the workmen arrive at the depth of sixty-three feet they come to a bed of chalk, which they bore with an augre five feet deep; they then withdraw from the pit before the augre is removed, and upon its extraction the water bursts up through the aperture with great violence, and quickly fills this new-made well, which continues full, and is affected neither by rains nor droughts. But that which is most remarkable in this operation is the layers of earth as we descend. At the depth of fourteen feet are found the ruins of an ancient city, paved streets, houses, floors, and different pieces of Mosaic. Under this is found a solid earth, that would induce one to think had never been removed; however, under it is found a soft oozy earth, made up of vegetables; and at twenty-six feet depth, large trees entire, such as walnut-trees, with the walnuts still sticking on the stem, and their leaves and branches in exact preservation. At twenty-eight feet deep a soft chalk is found, mixed with a vast quantity of shells; and this bed is eleven feet thick. Under this, vegetables are found again, with leaves and branches of trees as before; and thus alternately chalk and vegetable earth to the depth of sixty-three feet. These are the layers wherever the workmen attempt to bore; while in many of them they also find pieces of charcoal, bones, and bits of iron. From this description, therefore, it appears that this country has been alternately overflowed and deserted by the sea one age after another; nor were these overflowings and retirings of trifling depth or of short continuance. When the sea burst in, it must have been a long time in overwhelming the branches of the fallen forest with its sediment; and still longer in framing a regular bed of shells eleven feet over them. It must have therefore taken an age at least to make any one of these layers; and we may conclude, that it must have been many ages employed in the production of them all. The land also, upon being deserted, must have had time to grow compact, to gather fresh fertility, and to be drained of its waters before it could be disposed to vegetation, or before its trees could have shot forth again to maturity.

We have instances nearer home of the same kind given us in the Philosophical Transactions; one of them by Mr. Derham. An inundation of the sea at Dagenham, in Essex, laying bare a part of the adjacent pasture for above two hundred feet wide, and in some places twenty deep, it discovered a number of trees that had lain there for many ages before; these trees, by lying long under ground, were become black and hard, and their fibres so tough, that one might as easily break a wire as any of them; they lay so thick in the place where they were found, that in many parts he could step from one to another; he conceived, also, that not only all the adjacent marshes for several hundred acres were covered underneath with such timber, but also the marshes along the mouth of the Thames for several miles. The meeting with these trees at such depths he ascribes to the sediment of the river and the tides, which, constantly washing over them, have always left some part of their substance behind, so as, by repeated alluvions, to work a bed of vegetable earth over them to the height at which he found it.

The levels of Hatfield-Chace, in Yorkshire, a tract of above eighteen thousand acres, which was yearly overflowed, was reduced to arable and pasture land by one Sir Cornelius Vermusden, a Dutchman. At the bottom of this wide extent are found millions of the roots and bodies of trees, such as this island either formerly did or does at present produce. The roots of all stand in their proper postures; and by them, as thick as ever they could grow, the respective trunks of each, some

above thirty yards long. The oaks, some of which have been sold for fifteen pounds a-piece, are as black as ebony, very lasting, and close grained. The ash-trees are as soft as earth, and are commonly cut in pieces by the workmen's spades, and as soon as flung up into the open air turn to dust. But all the rest, even the willows themselves, which are softer than the ash, preserve their substance and texture to this very day. Some of the first appear to have vegetated even after they were fallen, and to have from their branches struck up trees as large as the parent trunk. It is observable that many of these trees have been burnt—some quite through, some on one side; some have been found chopped and squared, others riven with great wooden wedges—all sufficiently manifesting that the country which was deluged had formerly been inhabited. Near a great root of one tree were found eight coins of the Roman emperors; and in some places the marks of the ridge and furrow were plainly perceivable, which testified that the ground had formerly been patient of cultivation.

The learned naturalist who has given this description has pretty plainly evinced that this forest in particular must have been thus levelled by the Romans, and that the falling of the trees must have contributed to the accumulation of the waters. "The Romans," says he, "when the Britons fled, always pursued them into the fortresses of low woods and miry forests: in these the wild natives found shelter; and, when opportunity offered, issued out, and fell upon their invaders without mercy. In this manner the Romans were at length so harassed, that orders were issued out for cutting down all the woods and forests in Britain. In order to effect this, and destroy the enemy the easier, they set fire to the woods, composed of pines, which spreading, the conflagration destroyed not only the forest, but infinite numbers of the wretched inhabitants who had taken shelter therein. When the pine-trees had thus done what mischief they could, the Romans then brought their army nearer, and, with whole legions of the captive Britons, cut down most of the trees that were yet left standing—leaving only here and there some trees untouched as monuments of their fury. These, unneedful of their labour, being destitute of the underwood and of their neighbouring trees, were easily overthrown by the winds, and remained on the places where they happened to fall. The forest, thus fallen, must necessarily have stopped up the currents both from land and sea, and turned into great lakes what were before but temporary streams. The working of the waters here, the consumption and decay of rotten boughs and branches, and the vast increase of water-moss which flourishes upon marshy grounds, soon formed a covering over the trunks of the fallen trees, and raised the earth several feet above its former level. The earth thus every day swelling, by a continual increase from the sediment of the waters, and by the lightness of the vegetable substances of which it was composed, soon overtopped the waters by which this intumescence was at first effected; so that it entirely got rid of its inundations, or only demanded a slight assistance from man for that purpose." This may be the origin of all bogs, which are formed by the putrefaction of vegetable substances, mixed with the mud and slime deposited by waters, and at length acquiring a sufficient consistency.

From this we see what powerful effects the sea is capable of producing upon its shores, either by overflowing some or deserting others—by altering the direction of these, and rendering those craggy and precipitate which before were shelving. But the influence it has upon these is nothing to that which it has upon that great body of earth which forms its bottom. It is at the bottom of the sea that the greatest wonders are performed, and the most rapid changes are produced; it is there that the motion of the tides and the currents have

their whole force, and agitate the substances of which their bed is composed. But all these are almost wholly hid from human curiosity; the miracles of the deep are performed in secret; and we have but little information from its abysses, except what we receive by inspection at very shallow depths, or by the plummet, or from divers, who are known to descend from twenty to thirty fathoms.

The eye can reach but a very short way into the depths of the sea; and that only when its surface is glassy and serene. In many seas it perceives nothing but a bright sandy plain at the bottom, extending for several hundred miles, without an intervening object. But in others, particularly in the Red Sea, it is very different: the whole bottom of this extensive bed of waters is, literally speaking, a forest of sub-marine plants, and corals formed by insects for their habitation, sometimes branching out to a great extent. Here are seen the madrepores, the sponges, mosses, sea-mushrooms, and various other marine productions, covering every part of the bottom; so that some have even supposed the sea to have taken its name from the colour of its plants below. However, these plants are by no means peculiar to this sea, as they are found in great quantities in the Persian Gulf, along the coasts of Africa, and those of Provence and Catalonia.

The bottom of many parts of the sea near America presents a very different though a very beautiful appearance. This is covered with vegetables, which make it look as green as a meadow, and beneath are seen thousands of turtles and other sea animals feeding thereon.

In order to extend our knowledge of the sea to greater depths, recourse has been had to the plummet—which is generally made of a lump of lead of about forty pounds weight fastened to a cord. This, however, only answers in moderate depths; for when a deep sea is to be sounded, the matter of which the cord is composed, being lighter than the water, floats upon it, and, when let down to a considerable depth, its length so increases its surface that it is often sufficient to prevent the lead from sinking; so that this may be the reason that some parts of the sea are said to have no bottom.

In general, we learn from the plummet that the bottom of the sea is tolerably even where it has been examined; and that the farther from the shore the sea is in general the deeper. Notwithstanding, in the midst of a great and unfathomable ocean we often find an island raising its head, and singly braving its fury. Such islands may be considered as the mountains of the deep; and, could we for a moment imagine the waters of the ocean removed or dried away, we should probably find the inequalities of its bed resembling those that are found on land; here extensive plains—there valleys; and in many places mountains of amazing height. M. Buache has actually given us a map of that part of its bottom which lies between Africa and America, taken from the several soundings of mariners; in it we find that same uneven surface that we do upon land, the same eminences, and the same depressions. In such an imaginary prospect, however, there would be this difference—that as the tops of land-mountains appear the most barren and rocky, the tops of sea-mountains would be found the most verdant and fruitful.

The plummet, which thus gives us some idea of the inequalities of the bottom, leaves us totally in the dark as to every other particular; recourse, therefore, has been had to divers; these, either being bred up in this dangerous way of life, and accustomed to remain some time under water without breathing, or assisted by means of a diving-bell, have been able to return some confused and uncertain accounts of the places below. In the great diving-bell improved by Dr. Halley, which was large enough to contain five men, and was supplied with fresh air by buckets that alternately rose and fell, they de-

scended fifty fathoms. In this huge machine, which was let down from the mast of the ship, the doctor himself went down to the bottom, where, when the sea was clear, and especially when the sun shone, he could see perfectly well to write or read, and much more to take up anything that was underneath: at other times, when the water was troubled and thick, it was as dark as night below, so that he was obliged to keep a candle lighted at the bottom. But there was one thing very remarkable—that the water, which from above was usually seen of a green colour, when looked at from below appeared to him of a very different one, casting a redness upon one hand like that of damask roses—a proof of the sea's taking its colour not from anything floating in it, but from the different reflections of the rays of light. Upon the whole, the accounts we have received from the bottom by this contrivance are but few. We learn from it, and from divers in general, that while the surface of the sea may be deformed by tempests, it is usually calm and temperate below; that some divers who have gone down when the weather was calm, and came up when it was tempestuous, were surprised at their not perceiving the change at the bottom. This, however, must not be supposed to obtain with regard to the tides and the currents, as they are seen constantly shifting their bottom—taking their bed with great violence from one place and depositing it upon another. We are informed, also, by divers, that the sea grows colder in proportion as they descend to the bottom; that as far as the sun's rays pierce it is influenced by their warmth; but lower, the cold becomes almost intolerable. A person of quality, who had been himself a diver, as Mr. Boyle informs us, declared, that though he seldom descended above three or four fathoms, yet he found it so much colder than near the top that he could not well endure it; and that being let down in a great diving-bell, although the water could not immediately touch him, he found the air extremely cold upon his first arrival at the bottom.

From divers, also, we learn that the sea in many places is filled with rocks at bottom; and that among their cliffs and upon their sides various substances sprout forward, which are either really vegetables or the nests of insects, increased to some magnitude. Some of these assume the shape of beautiful flowers; and, though soft when taken up, soon harden, and are kept in the cabinets of the curious.

But of all those divers who have brought us information from the bottom of the deep, the famous Nicola Pesce, whose performances are told us by Kircher, is the most celebrated. I will not so much as pretend to vouch for the veracity of Kircher's account, which he assures us he had from the archives of the kings of Sicily; but it may serve to enliven a heavy chapter. "In the times of Frederic, king of Sicily, there lived a celebrated diver, whose name was Nicolas, and who, from his amazing skill in swimming, and his perseverance under water, was surnamed the "Fish." This man had from his infancy been used to the sea, and earned his scanty subsistence by diving for corals and oysters, which he sold to the villages on shore. His long acquaintance with the sea at last brought it to be almost his natural element. He frequently was known to spend five days in the midst of the waves, without any other provisions than the fish which he caught there, and ate raw. He often swam over from Sicily to Calabria, a tempestuous and dangerous passage, carrying letters from the king. He was frequently known to swim among the gulfs of the Lipari Islands, no way apprehensive of danger.

"Some mariners out at sea one day observed something at some distance from them, which they regarded as a sea-monster; but upon its approach it was known to be Nicolas Pesce, whom they took into their ship. When they asked him whither he was going in so stormy

and rough a sea, and at such a distance from land, he showed them a packet of letters which he was carrying to one of the towns of Italy, exactly done up in a leather bag in such a manner as that they could not be wetted by the sea. He kept them thus company for some time on their voyage, conversing and asking questions: and after eating a hearty meal with them he took his leave, and, jumping into the sea, pursued his voyage alone.

"In order to aid these powers of enduring in the deep, Nature seemed to have assisted him in a very extraordinary manner; for the spaces between his fingers and toes were webbed, as in a goose; and his chest became so very capacious, that he could take in at one inspiration as much breath as would serve him for a whole day.

"The account of so extraordinary a person did not fail to reach the King himself; who, actuated by the general curiosity, ordered that Nicolas should be brought before him. It was no easy matter to find him, who generally spent his time in the solitudes of the deep; but at last, however, after much searching, he was found and brought before his Majesty. The curiosity of this monarch had long been excited by the accounts he had heard of the bottom of the gulf of Charybdis; he therefore conceived that it would be a proper opportunity to have more certain information, and commanded our poor diver to examine the bottom of this dreadful whirlpool; as an incitement to his obedience, he ordered a golden cup to be flung into it. Nicolas was not insensible of the danger to which he was exposed—dangers best known only to himself—and he therefore presumed to remonstrate; but the hopes of the reward, the desire of pleasing the King, and the pleasure of showing his skill, at last prevailed. He instantly jumped into the gulf, and was swallowed as instantly up in its bosom. He continued for three quarters of an hour below, during which time the King and his attendants remained upon shore anxious for his fate; but he at last appeared, buffeting upon the surface, holding the cup in triumph in one hand, and making his way good among the waves with the other. It may be supposed he was received with applause upon his arrival on shore; the cup was made the reward of his adventure; the King ordered him to be taken proper care of; and, as he was somewhat fatigued and debilitated by his labour, after a hearty meal he was put to bed, and permitted to refresh himself by sleeping.

"When his spirits were thus restored, he was again brought to satisfy the King's curiosity with a narrative of the wonders he had seen; and his account was to the following effect:—He would never, he said, have obeyed the King's commands, had he been apprized of half the dangers that were before him. There were four things, he said, that rendered the gulf dreadful, not only to men, but even to the fishes themselves: first, the force of the water bursting up from the bottom, which requires great strength to resist; secondly, the abruptness of the rocks, that on every side threatened destruction; thirdly, the force of the whirlpool dashing against those rocks; and, fourthly, the number and magnitude of the poly-pous fish; some of which appeared as large as a man, and which, everywhere sticking against the rocks, projected their fibrous arms to entangle him. Being asked how he was able so readily to find the cup that had been thrown in, he replied that it happened to be flung by the waves into the cavity of a rock against which he himself was urged in his descent. This account, however, did not satisfy the King's curiosity: being requested to venture once more into the gulf for further discoveries, he at first refused; but the King, desirous of having the most exact information possible of all things to be found in the gulf, repeated his solicitations; and, to give them still greater weight, produced a larger cup than the

former, and added also a purse of gold. Upon these considerations, the unfortunate Pessacola once again plunged into the whirlpool, and was never heard of more."

## CHAP. XVIII.

### A SUMMARY ACCOUNT OF THE MECHANICAL PROPERTIES OF AIR.

Having described the earth and the sea, we now ascend into that fluid which surrounds them both; and which, in some measure, supports and supplies all Animated Nature. As upon viewing the bottom of the ocean from its surface we see an infinity of animals moving therein and seeking food, so, were some superior being to regard the earth at a proper distance, he might consider us in the same light; he might, from his superior station, behold a number of busy little beings, immersed in the aerial fluid that everywhere surrounds them, and sedulously employed in procuring the means of subsistence. This fluid, though too fine for the gross perception of its inhabitants, might, to his nicer organs of sight, be very visible; and, while he at once saw into its operations, he might smile at the varieties of human conjecture concerning it; he might readily discern, perhaps, the height above the surface of the earth to which this fluid atmosphere reaches; he might exactly determine that peculiar form of its parts which gives it the spring and elasticity with which it is endued; he might distinguish which of its parts were incorruptible air, and which only made for a little time to assume the appearance, so as to be quickly returned back to the element from whence it came. But as for us, who are immersed at the bottom of this gulf, we must be contented with a more confined knowledge; and, wanting a proper point of prospect, remain satisfied with a combination of the effects.

One of the first things that our senses inform us of is, that although the air is too fine for our sight, it is very obvious to our touch. Although we cannot see the wind contained in a bladder, we can very readily feel its resistance; and though the hurricane may want colour, we often fatally experience that it does not want force. We have equal experience of the earth's spring or elasticity: the bladder, when pressed, returns again upon the pressure being taken away; a bottle when filled often bursts, from the spring of air which is included.

So far the highest experience reaches; but, by carrying experiment a little farther, we learn that air also is heavy; a round glass vessel being emptied of its air, and accurately weighed, has been found lighter than when it was weighed with the air in it. Upon computing the superior weight of the full vessel, a cubic foot of air is found to weigh something more than an ounce.

From this experiment, therefore, we learn that the earth, and all things upon its surface, are everywhere covered with a ponderous fluid, which, rising very high over our heads, must be proportionably heavy. For instance, as in the sea, a man at the depth of twenty feet sustains a greater weight of water than a man at the depth of but ten feet; so will a man at the bottom of a valley have a greater weight of air over him than a man on the top of a mountain.

From hence we may conclude that we sustain a very great weight of air; and although, like men walking at the bottom of the sea, we cannot feel the weight which presses equally round us, yet the pressure is not the less real. As in morals, we seldom know the blessings that surround us till we are deprived of them; so here we do not perceive the weight of the ambient fluid till a part of it is taken away. If, by any means, we contrive

to take away the pressure of the air from any one part of our bodies, we are soon made sensible of the weight upon the other parts. Thus, if we clap our hand upon the mouth of a vessel from whence the air has been taken away, there will thus be air on one side and none on the other; upon which, we shall instantly find the hand violently sucked inwards; which is nothing more than the weight of the air upon the back of the hand that forces it into the space which is empty below.

As by this experiment we perceive that the air presses with great weight upon everything on the surface of the earth, so by other experiments we learn the exact weight with which it presses. First, if the air be exhausted out of any vessel, a drinking vessel for instance, and this vessel be set with the mouth downwards in water, the water will rise up into the empty space, and fill the inverted glass; for the external air will in this case press up the water where there is no weight to resist—as one part of a bed being pressed makes the other parts that have no weight upon them rise. In this case, as we said, the water being pressed without will rise in the glass; and would continue to rise (if the empty glass was tall enough) thirty-two feet high. In fact, there have been pipes made purposely for this experiment of above thirty-two feet high; in which, upon being exhausted, the water has always risen to the height of thirty-two feet; there it has always rested, and never ascended higher. From this, therefore, we learn that the weight of the air which presses up the waters is equal to a pillar or column of water which is thirty-two feet high, as it is just able to raise such a column, and no more. In other words, the surface of the earth is everywhere covered with a weight of air which is equivalent to a covering of thirty-two feet deep of water, or to a weight of twenty-nine inches and a half of quicksilver, which is known to be just as heavy as the former.

Thus we see that the air at the surface of the earth is just as heavy as thirty-two feet of water, or twenty-nine inches and a half of quicksilver; and it is easily found by computation, that to raise water thirty-two feet will require a weight of fifteen pounds upon every square inch. Now, if we are fond of computations, we have only to calculate how many square inches are in the surface of a human body; and allowing every inch to sustain fifteen pounds, we may amaze ourselves at the weight of air we sustain. It has been computed and found that our ordinary load of air amounts to within a little of forty thousand pounds. This is wonderful! but wondering is not the way to grow wise.

Although this be our ordinary load and our usual supply, there are at different times great variations. The air is not, like water, equally heavy at all seasons, but sometimes is lighter and sometimes more heavy. It is sometimes more compressed, and sometimes more elastic or springy, which produces the same effect as an increase of its weight. The air which at one time raises water thirty-two feet in the tube, and quicksilver twenty-nine inches, will not at another raise the one to thirty feet, or the other to twenty six inches. This makes therefore a very great difference in the weight we sustain; and we are actually known, by computation, to carry at one time four thousand pounds of air more than at another.

The reason of this surprising difference in the weight of air is either owing to its pressure from above, or to an increase of vapour floating in it. Its increased pressure is the consequence of its spring or elasticity, which cold and heat sensibly affect, and are continually changing.

This elasticity of the air is one of its most amazing properties, and to which it should seem nothing can set bounds. A body of air that may be contained in a nutshell may easily, with heat, be dilated into a sphere of unknown dimensions. On the contrary, the air contained in a house may be compressed into a cavity not larger than the eye of a needle. In short, no bounds can be set to its confinement or expansion—at least,

experiment has hitherto found its attempts indefinite. In every situation it retains its elasticity; and the more closely we compress it the more strongly does it resist the pressure. If to the increasing the elasticity on one side by compression we increase it on the other side by heat, the force of both soon becomes irresistible; and a certain French philosopher states that air thus confined and expanding was sufficient for the explosion of a world.

Many instruments have been formed to measure and determine these different properties of the air, and which serve several purposes. The barometer serves to measure its weight—to tell us when it is heavier and when lighter. It is composed of a glass tube or pipe, of about thirty inches in length, closed up at one end; this tube is then filled with quicksilver; this done, the maker, clapping his finger upon the open end, inverts the tube, and plunges the open end, finger and all, into a basin of quicksilver, and then takes his finger away. Now the quicksilver in the tube will, by its own weight, endeavour to descend into that in the basin; but the external air pressing on the surface of the quicksilver in the basin without, and no air being in the tube at top, the quicksilver will continue in the tube, being pressed up, as was said, by the air on the surface of the basin below. The height at which it is known to stand in the tube is usually about twenty-nine inches when the air is heavy; but not above twenty-six when the air is very light. Thus, by this instrument we can, with some exactness, determine the weight of the air, and, of consequence, tell before-hand the changes of the weather. Before fine dry weather, the air is charged with a variety of vapours, which float in it unseen, and render it extremely heavy, so that it presses upon the quicksilver; or, in other words, the barometer rises. In moist, rainy weather, the vapours are washed down, or there is not heat sufficient for them to rise, so that the air is then sensibly lighter, and presses up the quicksilver with less force; or, in other words, the barometer is seen to fall. Our constitutions seem also to correspond with the changes of the weather-glass; they are braced, strong, and vigorous, with a large body of air upon them; they are languid, relaxed, and feeble when the air is light, and refuses to give our fibres their proper tone.

But although the barometer thus measures the weight of the air with exactness enough for the general purposes of life, yet it is often affected with a thousand irregularities, that no exactness in the instrument can remedy, nor no theory account for. When high winds blow the quicksilver generally is low; it rises higher in cold weather than in warm, and is usually higher at morning and evening than at mid-day; it generally descends lower after rain than it was before it. There are also frequent changes in the air without any sensible alteration in the barometer.

As the barometer is thus used in predicting the changes of the weather, so it is also serviceable in measuring the heights of mountains, which mathematicians cannot so readily do; for, as the higher we ascend from the surface of the earth the air becomes lighter, so the quicksilver in the barometer will descend in proportion. It is found to sink at the rate of the tenth part of an inch for every ninety feet we ascend; so that in going up a mountain, if I find the quicksilver fallen an inch, I conclude that I am got upon an ascent of near nine hundred feet high. In this there has been found some variation, into a detail of which it is not the business of a natural historian to enter.

In order to determine the elasticity of air the wind-gun has been invented, which is an instrument variously made; but in all upon the principle of compressing a large quantity of air into a tube, in which there is an ivory ball, and then giving the compressed elastic air free power to act, and drive the ball as directed. The ball thus driven will pierce a thick board, and will be as fatal at small distances as if driven with gunpowder.

I do not know whether ever the force of this instrument has been assisted by means of heat; certain I am, that this, which could be very easily contrived by means of phosphorus, or any other hot substance applied to the barrel, would give such a force as I doubt whether gun-powder itself could produce.

The air-pump is an instrument contrived to exhaust the air from round a vessel adapted to that purpose called a receiver. This method of exhausting is contrived in the simple instrument by a piston, like that of a syringe, going down into the vessel, and thus pushing out its air; which, by means of a valve, is prevented from returning into the vessel again. But this, like all other complicated instruments, will be better understood by a minute inspection than an hour's description: it may suffice here to observe, that by depriving animals and other substances of all air, it shows us what the benefits and effects of air are in sustaining life or promoting vegetation.

The digester is an instrument of still more extraordinary effects than any of the former, and sufficiently discovers the amazing force of air, when its elasticity is augmented by fire. A common tea-kettle, if the spout were closed up and the lid put firmly down, would serve to become a digester, if strong enough. But the instrument used for this purpose is a strong metal pot, with a lid to screw close on, so that, when down, no air can get in or return; into this pot meat and bones are put, with a small quantity of water, and then the lid screwed close; a lighted lamp is put underneath, and, what is very extraordinary yet equally true, in six or eight minutes the whole mass, bones and all, are dissolved into a jelly; so great is the force and elasticity of the air contained within, struggling to escape, and breaking in pieces all the substances with which it is mixed. Care, however, must be taken not to heat this instrument too violently; for then the inclosed air would become irresistible, and burst the whole with perhaps a fatal explosion.

There are numberless other useful instruments made to depend on the weight, the elasticity, or the fluidity of the air, which do not come within the plan of the present work; the design of which is, not to give an account of the inventions that have been made for determining the nature and properties of air, but a mere narrative of its effects. The description of the pump, the forcing-pump, the fire-engine, the steam-engine, the syphon, and many others, belong not to the naturalist, but to the experimental philosopher: the one gives a history of Nature as he finds she presents herself to him, and he draws the obvious picture; the other pursues her with close investigation, tortures her by experiment to give up her secrets, and measures her latent qualities with laborious precision. Much more, therefore, might be said of the mechanical effects of air, and of the conjectures that have been made respecting the form of its parts; how some have supposed them to resemble little hoops coiled up in a spring; others, like fleeces of wool; others, that the parts are endued with a repulsive quality, by which, when squeezed together, they endeavour to fly off and recede from each other. We might have given the disputes relative to the height to which this body of air extends above us, and concerning which there is no agreement. We might have inquired how much of the air we breathe is elementary, and not reducible to any other substance; and of what density it would become if it were supposed to be continued down to the centre of the earth. At that place we might, with the help of figures and a bold imagination, have shown it twenty thousand times heavier than its bulk in gold; we might also prove it millions of times purer than upon earth when raised to the surface of the atmosphere. But these speculations do not belong to natural history; and they have hitherto produced no great advantages in that branch of science to which they more properly appertain.

## CHAP. XIX.

### AN ESSAY TOWARDS A NATURAL HISTORY OF THE AIR.

A late eminent philosopher has considered our atmosphere as one large chemical vessel, in which an infinite number of various operations are constantly performing. In it all the bodies of the earth are continually sending up a part of their substance by evaporation, to mix in this great alembic and to float awhile in common. Here minerals, from their lowest depths, ascend in noxious or in warm vapours to make a part of the general mass; seas, rivers, and subterranean springs furnish their copious supplies; plants receive and return their share; and animals—that, by living upon consume this general store—are found to give it back in greater quantities when they die. The air, therefore, that we breathe, and upon which we subsist, bears very little resemblance to that pure elementary body which was described in the last chapter, and which is rather a substance that may be conceived than experienced to exist. Air, such as we find it, is one of the most compounded bodies in all Nature. Water may be reduced to a fluid everyway resembling air by heat, which by cold becomes water again. Everything we see gives off its part to the air, and has a little floating atmosphere of its own round it. The rose is encompassed with a sphere of its odorous particles; while the nightshade infects the air with scents of a more ungrateful nature. The perfume of musk flies off in such abundance, that the quantity remaining becomes sensibly lighter by the loss. A thousand substances that escape all our senses we know to be there—the powerful emanations of the loadstone, the effluvia of electricity, the rays of light, and the insinuations of fire. Such are the various substances through which we move, and which we are constantly taking in at every pore, and returning again with imperceptible discharge!

This great solution or mixture of all earthly bodies is continually operating upon itself, which perhaps may be the cause of its unceasing motion; but it operates still more visibly upon such grosser substances as are exposed to its influence—for scarce any substance is found capable of resisting the corroding qualities of the air. The air, say the chymists, is a chaos furnished with all kinds of salts and menstrooms; and therefore it is capable of dissolving all kinds of bodies. It is well known that copper and iron are quickly covered and eaten with rust, and that in the climates near the equator no art can keep them clean. In those dreary countries, the instruments, knives, and keys that are kept in the pocket are nevertheless quickly encrusted; and the great guns, with every precaution, after some years become useless. Stones, as being less hard, may be readily supposed to be more easily soluble. The marble of which the noble monuments of Italian antiquity are composed, although in one of the finest climates in the world, show the impressions which have been made upon them by the air. In many places they seem worm-eaten by time, and in others they seem crumbling into dust. Gold alone seems to be exempted from this state of dissolution—it is never found to contract rust, though exposed never so long. The reason of this seems to be, that sea-salt—which is the only menstruum capable of acting upon and dissolving gold—is but very little mixed with the air; for salt being a very fixed body, and not apt to volatilize and rise with heat, there is but a small proportion of it in the atmosphere. In the laboratories and shops, however, where salt is much used and the air is impregnated with it, gold is found to rust as well as other metals.

Bodies of a softer nature are obviously destroyed by the air. Mr. Boyle says that silks brought to Jamaica will, if there exposed to the air, rot, even while they preserve their colour; but if kept therefrom, they retain both their strength and gloss. The same happens in

Brasil, where their clothes, which are black, soon turn of an iron colour, though in the shops they preserve their proper hue. In these tropical climates, also, such are the putrescent qualities of the air, that white sugar will sometimes be full of maggots. Drugs and plaisters lose their virtue, and become verminous. In some places they are obliged to expose their sweetmeats by day in the sun, otherwise the night air would quickly cause them to putrify. On the contrary, in the cold arctic regions animal substances during their winter are never known to putrify; and meat may be kept for months without any salt whatsoever. This experiment happily succeeded with the eight Englishmen who were accidentally left upon the inhospitable coasts of Greenland, at a place where seven Dutchmen had perished but a few years before; for, killing some rein-deer for their subsistence, and having no salt to preserve the flesh, to their great surprise they soon found it did not want any, as it remained sweet during their eight months' continuance upon that shore.

These powers with which air is endued over unorganized substances are exerted in a still stronger manner over plants, animals of an inferior nature, and, lastly, over man himself. Most of the beauty and the luxuriance of vegetation is well known to be derived from the benign influence of the air; and every plant seems to have its favourite climate not less than its proper soil. The lower ranks of animals also seem formed for their respective climates, in which only they can live. Man alone seems the child of every climate, and capable of existing in them all. However, this peculiar privilege does not exempt him from the influences of the air; he is as much subject to her malignity as the meanest insect or vegetable.

With regard to plants, air is so absolutely necessary for their life and preservation that they will not vegetate in an exhausted receiver. All plants have within them a quantity of air, which supports and agitates their juices. They are continually imbibing fresh nutriment from the air to increase this store, and to supply the wants which they sustain from evaporation. When, therefore, the external air is drawn from them, they are no longer able to subsist. Even that quantity of air which they before were possessed of escapes through their pores into the exhausted receiver; and as this continues to be pumped away they become languid, grow flaccid, and die. However, the plant or flower thus ceasing to vegetate is kept, by being secured from the external air, a much longer time sweet than it would have continued had it been openly exposed.

That air which is so necessary to the life of vegetables is still more so to that of animals; there are none found, how seemingly torpid soever, that do not require their needful supply. Fishes themselves will not live in water from whence the air is exhausted; and it is generally supposed that they die in frozen ponds from the want of this necessary to animal existence. Many have been the animals that idle curiosity has tortured in the prison of a receiver, merely to observe the manner of their dying. We shall, from a thousand instances, produce that of the viper, as it is known to be one of the most voracious reptiles in the world, and as we shall feel but little compassion for its tortures. Mr. Boyle took a new-caught viper, and, shutting it up into a small receiver, began to pump away the air. "At first, upon the air's being drawn away, it began to swell; some time after he had done pumping it began to gape, and open its jaws; being thus compelled to open its jaws, it once more resumed its former lankness; it then began to move up and down within, as if to seek for air, and after a while foamed a little, leaving the foam sticking to the inside of the glass; soon after the body and neck grew prodigiously tumid, and a blister appeared upon its back; an hour and a half after the receiver was exhausted the distended viper moved, and gave manifest

signs of life; the jaws remained quite distended; as it were from beneath the epiglottis came the black tongue, and reached beyond it; but the animal seemed by its posture not to have any life; the mouth, also, was grown blackish within; and in this situation it continued for twenty-three hours. But upon the air's being readmitted the viper's mouth was presently closed, and soon after opened again; and for some time these motions continued, which argued the remains of life." Such is the fate of the most insignificant or minute reptile that can be thus included. Mites, fleas, and even the little eels that are found swimming in vinegar, die for want of air. Not only these, but the eggs of these animals, will not produce in vacuo, but require air to bring them to perfection.

As in this manner air is necessary to their subsistence, so also it must be of a proper kind, and not impregnated with foreign mixtures. That factitious air which is pumped from plants or fluids is generally in a short time fatal to them. Mr. Boyle has given us many experiments to this purpose. After having shown that all vegetable and most mineral substances, properly prepared, may afford air by being placed in an exhausted receiver, and this in such quantities, that some have thought it a new substance, made by the alteration which the mineral or plant has undergone by the texture of its parts being loosened in the operation—having shown, I say, that this air may be drawn in great quantities from vegetable, animal, or mineral substances, such as apples, cherries, amber burnt, or hartshorn—he included a frog in artificial air, produced from paste; in seven minutes' space it suffered convulsions, and at last lay still, and, being taken out, recovered no motion at all, but was dead. A bird enclosed in artificial air, from raisins, died in a quarter of a minute, and never stirred more. A snail was put into the receiver, with air of paste; in four minutes it ceased to move, and was dead, although it had survived in vacuo for several hours—so that factitious air proved a greater enemy to animals than even a vacuum itself.

Air, also, may be impregnated with fumes that are instantly fatal to animals. The fumes of hot iron, copper, or any other heated metal, blown into the place where an animal is confined, instantly destroy it. We have already mentioned the vapours in the grotto Del Cane suffocating a dog. The ancients even supposed that these animals, as they always ran with their noses to the ground, were the first that felt any infection. In short, it should seem that the predominance of any one vapour from any body, how wholesome soever in itself, becomes infectious; and that we owe the salubrity of the air to the variety of its mixture.

But there is no animal whose frame is more sensibly affected by the changes of the air than man. It is true, he can endure a greater variety of climates than the lower orders generally are able to do; but it is rather by the means which he has discovered of obviating their effects, than by the apparent strength of his constitution. Most other animals can bear cold or hunger better, endure greater fatigues in proportion, and are satisfied with shorter repose. The variations of the climate, therefore, would probably effect them less, if they had the same means or skill in providing against the severities of the change. However this be, the body of man is an instrument much more nicely sensible of the variations of the air than any of those which his own art has produced; for his frame alone seems to unite all their properties, being invigorated by the weight of the air, relaxed by its moisture, enfeebled by its heat, and stiffened by its frigidity.

But it is chiefly by the predominance of some peculiar vapour that the air becomes unfit for human support. It is often found by dreadful experience to enter into the constitution, to mix with its juices, and to putrify the whole mass of blood. The nervous system is not

less affected by its operations; palsies and vertigoes are caused by its damps; and a still more fatal train of distempers by its exhalations. In order that the air should be wholesome, it is necessary, as we have seen, that it should not be of one kind, but the compound of several substances; and the more various the composition, to all appearance the more salubrious. A man, therefore, who continues in one place is not so likely to enjoy this wholesome variety as he who changes his situation, and, if I may so express it, instead of waiting for a renovation of air, walks forward to meet his arrival. This mere motion, independent even of the benefits of exercise, becomes wholesome, by thus supplying a great variety of that healthful fluid by which we are sustained.

A thousand accidents are found to increase these bodies of vapour, that make one place more or less wholesome than another. Heat may raise them in too great quantities; and cold may stagnate them. Minerals may give off their effluvia in such proportion as to render the air unwholesome by their supply; and animal putrefaction seems to furnish a quantity of vapour, at least as noxious as any of the former. All these united generally make up the mass of respiration, and are, when mixed together, harmless; but any one of them, for a long time singly predominant, becomes at length fatal.

The effects of heat in producing a noxious quality in the air are well known. Those torrid regions under the Line are always unwholesome. At Senegal, I am told, the natives consider forty as a very advanced time of life, and generally die of old age at fifty. At Carthage, in America, where the heat of the hottest day ever known in Europe is continual—where, during their winter season, these dreadful heats are united with a continual succession of thunder, rain, and tempests, arising from their intenseness—the wan and livid complexions of the inhabitants might make strangers suspect that they were just recovered from some dreadful distemper. The actions of the natives are conformable to their colour; in all their motions they are somewhat relaxed and languid; the heat of the climate even affects their speech, which is soft and slow, and their words generally broken. Travellers from Europe retain their strength and ruddy colour in that climate possibly for three or four months; but afterwards suffer such decays in both, that they are no longer to be distinguished from the inhabitants by their complexion. However, this languid and spiritless existence is frequently drawn out sometimes even to eighty. Young persons are generally most affected by the heat of the climate, which spares the more aged; but all, upon their arrival on the coasts, are subject to the same train of fatal disorders. Few nations have experienced the mortality of these coasts so much as our own; in our unsuccessful attack upon Carthage, more than three parts of our army were destroyed by the climate alone; and those that returned from that fatal expedition found their former vigour irretrievably gone. In our more fortunate expedition, which gave us the Havannah, we had little reason to boast of our success; instead of a third, not a fifth part of the army were left survivors of their victory, the climate being an enemy that even heroes cannot conquer.

The distempers that thus proceed from the cruel malignity of those climates are many; that, for instance, called the "chopotonadas," carries off a multitude of people, and extremely thins the crews of European ships whom gain tempts into those inhospitable regions. The nature of this distemper is but little known, being caused in some persons by cold, in others by indigestion. But its effects are far from being obscure; it is generally fatal in three or four days. Upon its seizing the patient it brings on what is there called the "black vomit," which is the sad symptom after which none are ever known to recover. Some, when the vomit attacks them, are seized with a delirium that, were they not tied down,

they would tear themselves to pieces, and thus expire in the midst of this furious paroxysm. This disorder in milder climates takes the name of the "bilious fever," and is attended with milder symptoms, but is very dangerous in all.

There are many other disorders incident to the human body that seem the offspring of heat; but to mention no other, that very lassitude which prevails in all the tropical climates may be considered as a disease. The inhabitants of India, says a modern philosopher, sustain an unceasing languor from the heats of their climate, and are torpid in the midst of profusion. For this reason, the great Disposer of Nature has clothed their country with trees of an amazing height, whose shade might defend them from the beams of the sun, and whose continued freshness might in some measure temper their fierceness. From these shades, therefore, the air receives refreshing moisture, and animals a cooling protection. The whole race of savage animals retire in the midst of the day to the very centre of the forests, not so much to avoid their enemy man as to find a defence against the raging heats of the season. This advantage which arises from shade in torrid climates may probably afford a solution for that extraordinary circumstance related by Boyle, which he imputes to a different cause. In the island of Ternate, belonging to the Dutch—a place that had long been celebrated for its beauty and healthfulness—the clove-trees grew in such plenty, that they in some measure lessened their own value; for this reason—the Dutch resolved to cut down the forests, and thus to raise the price of the commodity; but they had soon reason to repent of their avarice—for such a change ensued (by cutting down the trees), that the whole island, from being healthy and delightful, having lost its charming shades, became extremely sickly, and has actually continued so to this day. Boerhaave considered heat so prejudicial to health, that he was never seen to go near a fire.

An opposite set of calamities are the consequence in climates where the air is condensed by cold. In such places, all that train of distempers which are known to arise from obstructed perspiration are very common—eruptions, boils, scurvy, and a loathsome leprosy that covers the whole body with a scurf and white putrid ulcers. These disorders also are infectious; and, while they thus banish the patient from society, they generally accompany him to the grave. The men of these climates seldom attain the age of fifty; but the women, who do not lead such laborious lives, live longer.

The autumnal complaints which attend a wet summer indicate the dangers of a moist air. The long continuance of an east wind also shows the prejudice of a dry one. Mineral exhalations, when copious, are everywhere known to be fatal; and although we probably owe the increase and luxuriance of vegetation to a moderate degree of their warmth, yet the natives of those countries where there are mines in plenty but too often experience the noxious effects of their vicinity. Those trades that deal in the preparation of metals of all kinds are always unwholesome; and the workmen, after a short time, are generally seen to labour under palsies and other nervous complaints. The vapours from some vegetables are well known to be attended with dangerous effects. The shade of the machinel-tree, in America, is said to be fatal, as was that of the juniper, if we may credit the ancients. Those who walk through fields of poppies, or in any manner prepare those flowers for making opium, are very sensibly affected with the drowsiness they occasion. A physician of Mr. Boyle's acquaintance, causing a large quantity of black hellebore to be pounded in a mortar, most of the persons who were in the room, and especially the person who pounded it, were purged by it, and some of them strongly. He also gathered a certain plant in Ireland, which the person who beat it in a mortar and the physician

who was standing near were so strongly effected by, that their hands and faces swelled to an enormous size, and continued tumid for a long time after.

But neither mineral nor vegetable steams are so dangerous to the constitution as those proceeding from animal substances, putrefying either by disease or death. The effluvia that comes from diseased bodies propagate that frightful catalogue of disorders which are called "infectious." The parts which compose vegetable vapours and mineral exhalations seem gross and heavy in comparison of these volatile vapours, that go to great distances, and have been described as spreading desolation over the whole earth. They fly everywhere—penetrate everywhere; and the vapours that fly from a single disease soon render it epidemic.

The plague is the first upon the list in this class of human calamities. From whence this scourge of man's presumption may have its beginning is not well known; but we well know that it is propagated by infection. Whatever be the general state of the atmosphere, we learn from experience that the noxious vapours, though but singly introduced at first, taint the air by degrees: every person infected tends to add to the growing malignity; and as the disorder becomes more general the putrescence of the air becomes more noxious, so that the symptoms are aggravated by continuance. When it is said that the origin of this disorder is unknown, it implies that the air seems to be but little employed in first producing it. There are some countries, even in the midst of Africa, that we learn have never been infected with it, but continue for centuries unmolested. On the contrary, there are others that are generally visited once a year, as in Egypt—which, nevertheless, seems peculiarly blessed with the serenity and temperance of its climate. In the former countries, which are of vast extent, and many of them very populous, everything should seem to dispose the air to make the plague continual among them—the great heats of the climate, the unwholesomeness of the food, the sloth and dirt of the inhabitants, but, above all, the bloody battles which are continually fought among them, after which heaps of dead bodies are left unburied, and exposed to putrefaction. All these one might think would be apt to bring the plague among them; and yet we are assured by Leo Africanus, that in Numidia the plague is not known once in a hundred years; and that in Negroland it is not known at all. This dreadful disorder, therefore, must have its rise, not from any previous disposition of the air, but from some particular cause, beginning with one individual, and extending the malignity by communication, till at last the air becomes actually tainted by the generality of the infection.

The plague which spread itself over the whole world in the year 1346, as we are told by Mezeray, was so contagious that scarce a village, or even a house, escaped being infected by it. Before it had reached Europe, it had been for two years travelling from the great kingdom of Cathay, where it began by a vapour most horribly foetid; this broke out of the earth like a subterranean fire, and upon the first instant of its eruption consumed and desolated above two hundred leagues of that country, even to the trees and stones.

In that great plague which desolated the city of London in the year 1665, a pious and learned school master of Mr. Boyle's acquaintance, who ventured to stay in the city, and took upon him the humane office of visiting the sick and the dying who had been deserted by better physicians, averred, that being once called to a poor woman who had buried her children of the plague, he found the room where she lay so little that it scarce could hold any more than the bed whereon she was stretched. However, in this wretched abode, beside her, in an open coffin, her husband lay, who had some time before died of the same disease; and whom she, poor creature, soon followed. But what showed the pecu-

liar malignity of the air thus suffering from animal putrefaction was, that the contagious steams had produced spots on the very wall of their wretched apartment; and Mr. Boyle's own study, which was contiguous to a pest-house, was also spotted in the same frightful manner. Happily for mankind, this disorder for more than a century has not been known in our island; and for this last age has abated much of its violence, even in those countries where it is most common. Diseases, like empires, have their revolutions; and those which for a while were the scourge of mankind sink unheard of, to give place to new ones more dreadful, as being less understood.

For this revolution in disorders, which has employed the speculation of many, Mr. Boyle accounts in the following manner:—"Since," says he, "there want not causes in the bowels of the earth to make considerable change amongst the materials that Nature has plentifully treasured up in those magazines, and as those noxious steams are abundantly supplied to the surface, it may not seem improbable that in this great variety some may be found capable of particularly affecting the human frame in a particular manner, and thus of producing new diseases. The duration of these may be greater or less, according to the lastingness of those subterraneous causes that produced them. On which account, it need be no wonder that some diseases have but a short duration, and vanish not long after they appear; whilst others may continue longer, as having under ground more settled and durable causes to maintain them."

From the recital of this train of mischiefs produced by the air upon minerals, plants, animals, and man himself, a gloomy mind may be apt to dread this indulgent nurse of Nature as a cruel and an inexorable step-mother; but it is far otherwise; and, although we are sometimes injured, yet almost all the comforts and blessings of life spring from its propitious influence. It would be needless to observe, that it is absolutely necessary for the support of our lives; for of this, every moment's experience assures us. But how it contributes to this support is not so readily comprehended. All allow it to be a friend to whose benefits we are constantly obliged; and yet, to this hour, philosophers are divided as to the nature of the obligation. The dispute is whether the air is only useful by its weight to force our juices into circulation; or whether, by containing a peculiar spirit, it mixes with the blood in our vessels, and acts like a spur to their industry. Perhaps it may exert both these useful offices at the same time. Its weight may give the blood its progressive motion through the larger vessels of the body, and its admixture with it cause those contractions of all the vessels which serve to force it still more strongly forward through the minutest channels of the circulation. Be this as it may, it is well known that that part of our blood which has just received the influx of the air in our bodies is of a very different colour from that which has almost performed its circuit. It has been found that the arterial blood which has been immediately mixed with the air in the lungs, and, if I may so express it, is just beginning its journey through the body, is of a fine florid scarlet colour; while, on the contrary, the blood of the veins that is returning from having performed its duty is of a blackish crimson hue. Whence this difference of colour should proceed is not well understood; we only know the fact that this florid colour is communicated by the air; and we are well convinced that this air has been admitted into the blood for very useful purposes.

Besides this vital principle in animals, the air also gives life and body to flame. A candle quickly goes out in an exhausted receiver; for having soon consumed the quantity of air, it then expires for want of a fresh supply. There has been a flame contrived that will burn under water: but none yet has been found that will continue

to burn without air. Gunpowder, which is the most catching and powerful fire we know, will not go off in an exhausted receiver; nay, if a train of gunpowder be laid so as that one part may be fired in the open air, yet the other part in *vacuo* will remain untouched and unconsumed. Wood, also, set on fire immediately goes out; and its flame ceases upon removing the air; for something is then wanting to press the body of the fire against that of the fuel, and to prevent the too speedy diffusion of the flame. We frequently see cooks, and others whose business it is to keep up strong fires, take proper precautions to exclude the beams of the sun from shining upon them, which effectually puts them out. This they are apt to ascribe to a wrong cause—namely, the operation of the light; but the real fact is, that the warmth of the sun-beams lessen and dissipate the body of the air that goes to feed the flame, and the fire, of consequence, languishes for want of a necessary supply.

The air, while it thus kindles fire into flame, is nevertheless found to moderate the rays of light, to dissipate their violence, and to spread an uniform lustre over every object. Were the beams of the sun to dart directly upon us without passing through this protecting medium, they would either burn us up at once or blind us with their effulgence. But by going through the air they are reflected, refracted, and turned from their direct course a thousand different ways; and thus are more evenly diffused over the face of Nature.

Among the other necessary benefits the air is of to us, one of the principal is its conveyance of sound. Even the vibrations of a bell (which have the loudest effect that we know of) ceases to be heard when under the receiver of an air-pump. Thus all the pleasures we receive from conversation with each other, or from music, depend entirely upon the air.

Odours, likewise, are diffused only by the means of air; without this fluid to swim in they would for ever remain torpid in their respective substances—and the rose would affect us with as little sensations of pleasure as the thorn on which it grew.

Those who are willing to augment the catalogue of the benefits we receive from this element assert, also, that tastes would be insipid were it not that the air presses their parts upon the nerves of the tongue and palate, so as to produce their grateful effects. Thus, continue they, upon the tops of high mountains, as on the Peak of Teneriffe, the most poignant bodies—as pepper, ginger, salt, and spice—have no sensible taste, for want of their particles being thus sent home to the sensory. But we owe the air sufficient obligations not to be careful in admitting this among the number. In fact, all substances have their taste, as well on the tops of the mountains as in the bottom of the valley; and I have been one of many who have eaten a very savoury dinner on the Alps.

It is sufficient, therefore, that we regard the air as the parent of health and vegetation, as a kind dispenser of light and warmth, and as the conveyer of sounds and odours. This is an element of which Avarice will not deprive us, and which Power cannot monopolise. The treasures of the earth, the verdure of the fields, and even the refreshments of the stream, are too often seen going to assist the luxuries of the great; while the less fortunate part of mankind stand humble spectators of their encroachments. But the air no limitations can bound, nor any land-marks restrain. In this benign element all mankind can boast an equal possession; and for this we all have equal obligations to Heaven. We consume a part of it for our own sustenance while we live; and when we die, our putrefying bodies give back the supply which, during life, we had accumulated from the general mass.

## CHAP. XX.

## OF WINDS, IRREGULAR AND REGULAR.

Wind is a current of air. Experimental philosophers produce an artificial wind by an instrument called an "æolipile." This is nothing more than a hollow copper ball with a long pipe (a tea-kettle might be readily made into one, if it were entirely closed at the lid and the spout left open); through this spout it is to be filled with water and then set upon the fire, by which means it produces a violent blast, like wind, which continues while there is any water remaining in the instrument. In this manner water is converted into a rushing air, which, if caught as it goes out and left to cool, is again quickly converted into its former element. Besides this, as was mentioned in the former chapter, almost every substance contains some portion of air. Vegetables or the bodies of animals left to putrify produce it in a very copious manner. But it is not only seen thus escaping from bodies, but it may be very easily made enter into them. A quantity of air may be compressed into water so as to be intimately blended with it. It finds a much easier admission into wine, or any fermented liquor; and an easier still into spirits of wine. Some salts suck up the air in such quantities that they are made sensibly heavier thereby, and often are melted by its moisture. In this manner, most bodies being found either capable of receiving or affording it, we are not to be surprised at those streams of air that are continually floating round the globe. Minerals, vegetables, and animals contribute to increase the current, and are sending off their constant supplies. These, as they are differently affected by cold or heat, by mixture or putrefaction, all yield different quantities of air at different times; and the loudest tempests and most rapid whirlwinds are formed for their united contributions.

The sun is the principal instrument in rarifying the juices of plants, so as to give an escape to their imprisoned air; it is also equally operative in promoting the putrefaction of animals. Mineral exhalations are more frequently raised by subterranean heat. The moon, the other planets, the seasons, are all combined in producing these effects in a smaller degree. Mountains give a direction to the courses of the air; fires carry a current of air along their body; night and day alternately chill and warm the earth, and produce an alternate current of its vapours. These and many other causes may be assigned for the variety and the activity of the winds, their continual change, and their uncertain duration.

With us on land, as the wind proceeds from so many causes, and meets such a variety of obstacles, there can be but little hopes of ever bringing its motions to conform to theory, or of foretelling how it may blow a minute to come. The great Bacon, indeed, was of opinion, that by a close and regular history of the winds, continued for a number of ages together, and the particulars of each observation reduced to general maxims, we might at last come to understand the variations of this capricious element; and that we could foretell the certainty of a wind with as much ease as we now foretell the return of an eclipse. Indeed, his own beginnings in this arduous undertaking seem to speak the possibility of its success; but, unhappily for mankind, this investigation is the work of ages, and we want a Bacon to direct the process.

To be able, therefore, with any plausibility to account for the variations of the wind upon land is not to be at present expected; and to understand anything of their nature, we must have recourse to those places where they are more permanent and steady. This uniformity and steadiness we are chiefly to expect upon the ocean. There, where there is no variety of substances to furnish the air with various and inconstant supplies—where

there are no mountains to direct the course of its current, but where all is extensively uniform and even, in such a place, the wind arising from a simple cause must have but one simple motion: in fact, we find it so. There are many parts of the world where the winds that with us are so uncertain pay their stated visits. In some places they are found to blow one way by day and another by night; in others, for one half of the year they go in a direction contrary to their former course; but what is more extraordinary still, there are some places where the winds never change, but for ever blow the same way. This is particularly found to obtain between the tropics in the Atlantic and Æthiopic oceans, as well as in the great Pacific Sea.

Few things can appear more extraordinary to a person who has never been out of our variable latitudes than this steady wind, that for ever sits in the sail, sending the vessel forward, and as effectually preventing its return. He who has been taught to consider that nothing in the world is so variable as the winds, must certainly be surprised to find a place where there is nothing more uniform. With us their inconstancy has become a proverb; with the natives of those distant climates they may talk of a friend or a mistress as fixed and unchangeable as the winds, and mean a compliment by the comparison. When our ships are once arrived into the proper latitudes of the great Pacific Ocean, the mariner forgets the helm, and his skill becomes almost useless, neither storms nor tempests are known to deform the glassy bosom of that immense sheet of waters; a gentle breeze, that for ever blows in the same direction, rests upon the canvas, and speeds the navigator. In the space of six weeks ships are thus known to cross an immense ocean, which takes more than so many months to return. Upon returning, the trade-wind, which has been propitious, is then avoided; the mariner is generally obliged to steer into the northern latitudes, and to take the advantage of every causal wind that offers to assist him into port. This wind, which blows with such constancy one way, is known to prevail not only in the Pacific Ocean, but also in the Atlantic, between the coasts of Guinea and Brazil, and likewise in the Æthiopic Ocean. This seems to be the great universal wind, blowing from the east to the west, that prevails in all the extensive oceans where the land does not frequently break the general current. Were the whole surface of the globe an ocean there would probably be but this one wind—for ever blowing from the east, pursuing the motions of the sun westward. All the other winds seem subordinate to this; and many of them are made from the deviations of its current. To form, therefore, any conception relative to the variation of the wind in general, it is proper to begin with that which never varies.

There have been many theories to explain this invariable motion of the winds; among the rest, we cannot omit that of Dr. Lyster, for its strangeness. "The sea," says he, "in those latitudes is generally covered over with green weeds for a great extent; and the air emitted from the vegetable perspiration of these produces the trade-wind." The theory of Cartesius was not quite so absurd. He alleged that the earth went round faster than its atmosphere at the equator; so that its motion from west to east gave the atmosphere an imaginary one from east to west; and thus an east wind was eternally seen to prevail. Rejecting these arbitrary opinions—conceived without force and asserted without proof—Dr. Halley has given one more plausible, which seems to be the reigning system of the day.

To conceive his opinion clearly, let us for a moment suppose the whole surface of the earth to be an ocean, and the air encompassing it on every side without motion. Now it is evident that that part of the air which lies directly under the beams of the sun will be rarified; and if the sun remained for ever in the same place,

there would be a great vacuity in the air, if I may so express it, beneath the place where the sun stood. The sun moving forward from east to west, this vacuity will follow too, and still be made under it. But while it goes on to make new vacuities, the air will rush in to fill up those the sun has already made; in other words, as it is still travelling forward the air will be continually rushing in behind, and pursue its motions from east to west. In this manner the air is put into motion by day; and by night the parts continue to impel each other till the next return of the sun, which gives a new force to the circulation.

In this manner is explained the constant east wind that is found blowing round the globe near the equator. But it is also known, that as we recede from the equator on either side we come into a trade-wind that continually blows from the poles, from the north on one side or the south on the other—both directing towards the equator. This also proceeds from a similar cause with the former; for the air being more rarified in those places over which the sun more directly darts its rays, the currents will come both from the north and the south to fill up the intermediate vacuity.

These two motions—namely, the general one from east to west and the more particular one from both the poles—will account for all the phenomena of trade-winds; which, if the whole surface of the globe were sea, would undoubtedly be constant, and for ever continue to blow in one direction. But there are a thousand circumstances to break these air currents into smaller ones; to drive them back against their general course; to raise or depress them; to condense them into storms, or to whirl them in eddies. In consequence of this, regard must be often had to the nature of the soil, the position of the high mountains, the course of the rivers, and even to the luxuriance of vegetation.

If a country lying directly under the sun be very flat and sandy, and if the land be low and extensive, the heats occasioned by the reflection of the sun-beams produce a very great rarefaction of the air. The deserts of Africa, which are conformable to this description, are scarce ever fanned by a breath of wind by day; but the burning sun is continually seen blazing in intolerable splendour above them. For this reason, all along the coasts of Guinea the wind is always perceived blowing in upon land, in order to fill up the vacuity caused by the sun's operation. On those shores, therefore, the wind blows in a contrary direction to that of its general current, and is constantly found setting in from the west.

From the same cause it happens that those constant calms, attended with deluges of rain, are found in the same part of the ocean; for this tract being placed in the middle, between the westerly winds blowing on the coast of Guinea and the easterly trade-winds that move at some distance from shore in a contrary direction, the tendency of that part of the air which lies between these two opposite currents is indifferent to either, and so rests between both in torpid serenity; and the weight of the incumbent atmosphere being diminished by the continual contrary winds blowing from hence, it is unable to keep the vapours suspended that are copiously borne thither, so that they fall in continual rains.

But it is not to be supposed that any theory can account for all the phenomena of even those winds that are known to be most regular. Instead of a complete system of the trade-winds, we must rather be content with an imperfect history. These, as was said, being the result of a combination of effects, assume as great a variety as the causes producing them are various.

Besides the great general wind above mentioned, in parts of the Atlantic which lie under the temperate zone a north wind prevails constantly during the months of October, November, December, and January. These, therefore, are the most favourable months for embarking

for the East Indies, in order to take the benefit of these winds for crossing the line; and it has been found by experience that those who had set sail five months before were not in the least farther advanced in their voyage than those who waited for the favourable wind. During the winter of Nova Zembla and the other arctic countries a north wind reigns almost continually. In the Cape de Verde islands a south wind prevails during the month of July. At the Cape of Good Hope a north-west wind blows during the month of September. There are also regular winds, produced by various causes, upon land. The ancient Greeks were the first who observed a constant breeze, produced by the melting of the snows in some high countries. This was perceived in Greece, Thrace, Macedonia, and the *Ægean Sea*. The same kinds of winds are now remarked in the kingdom of Congou and the most southern parts of Africa. The flux and reflux of the sea also produces some regular winds that serve the purposes of trade; and in general it may be observed, that wherever there is a strong current of water there is a current of air that seems to attend it.

Besides these winds that are found to blow in one direction, there are, as was said before, others that blow for certain months of the year one way, and the rest of the year the contrary way; these are called the "Monsoons," from a famous pilot of that name, who first used them in navigation with success. In all that part of the ocean which lies between Africa and India, the east winds begin in the month of January, and continue till about the commencement of June. In the month of August or September the contrary direction takes place; and the west winds prevail for three or four months. The interval between these winds—that is to say, from the end of June to the beginning of August—there is no fixed wind; but the sea is usually tossed by violent tempests proceeding from the north. These winds are always subject to their greatest variations as they approach the land; so that on one side the great peninsula of India the coasts are for near half the year harrassed by violent hurricanes and northern tempests; while on the opposite side, and all along the coasts of Coromandel, these dreadful tempests are wholly unknown. At Java and Ceylon, a west wind begins to reign in the month of September; but at fifteen degrees of south latitude this wind is found to be lost, and the great general trade-wind from the east is perceived to prevail. On the contrary, at Cochin, in China, the west wind begins in March; so that these Monsoons prevail at different seasons throughout the Indies. The mariner takes one part of the way to go from Java to the Moluccas; another from Cochin to Molucca; another from Molucca to China; and still another to direct him from China to Japan.

There are winds, also, that may be considered as peculiar to certain coasts; for example, the south wind is almost constant upon the coasts of Chili and Peru; western winds almost constantly prevail on the coast of *Terræ Magellanica*, and in the environs of the Straits le Maire. On the coasts of Malabar north and north-west winds prevail continually; along the coast of Guinea the north-west wind is also very frequent; and, at a distance from the coasts, the north-east is always found prevailing. From the beginning of November to the end of December a west wind prevails on the coasts of Japan; and during the whole winter no ships can leave the port of Cochin on account of the impetuosity of the winds that set upon the coast. These blow with such vehemence that the ports are entirely choked up with sand, and even boats are not able to enter. However, the east winds that prevail for the half of the year clear the mouths of their harbours from the accumulations of the preceding winter, and set the confined ships at liberty. At the Straits of Babelmandel there is a south wind that periodically returns, and which is always followed by a north-east.

Beside winds thus peculiar to certain coasts, there are others found to prevail on all the coasts in warm climates, which during the one part of the day blow from the shore, and during another part of it blow from the sea. The sea-breeze in those countries, as Dampier observes, commonly arises in the morning, about nine o'clock, proceeding slowly in a fine small black curl upon the surface of the water, and making its way to refresh the shore. It is gentle at first, but increases gradually till twelve o'clock, then insensibly sinks away, and is totally hushed at five. Upon its ceasing the land-breeze begins to take its turn, which increases gradually till twelve at night, and is succeeded in the morning by the sea-breeze again. Without doubt, nothing could be more fortunate for the inhabitants of the warm countries where those breezes blow than this alternate refreshment, which they feel at those seasons when it is most wanted. The heat on some coasts would be insupportable were it not for such a supply of air, when the sun has rarified all that which lay more immediately under the coast. The sea-breeze temperates the heat of the sun by day, and the land-breeze corrects the malignity of the dews and vapours by night. Where these breezes, therefore, prevail (and they are very common) the inhabitants enjoy a share of health and happiness unknown to those that live much farther up the country, or such as live in similar latitudes without this advantage. The cause of these obviously seems to arise from the rarefaction of the air by the sun, as their duration continues with its appearance and alters when it goes down—the sun, it is observed, equally diffusing his beams upon land and sea, the land, being a more solid body than the water, receives a greater quantity of heat, and reflects it more strongly. Being thus, therefore, heated to a greater degree than the waters, it of consequence drives the air from land out to sea; but, its influence being removed, the air returns to fill up the former vacuity. Such is the usual method of accounting for this phenomenon; but unfortunately the sea and land breezes are visitants that come at all hours. On the coasts of Malabar, the land-breezes begin at midnight and continue till noon; then the sea-breezes take their turn, and continue till midnight. While again, at Congou, the land-breezes begin at five and continue till nine the following day.

But if the cause of these be so inscrutable—which are, as we see, tolerably regular in their visitations—what shall we say to the winds of our own climate, that are continually shifting and incapable of rest? Some general causes may be assigned, which nothing but particular experience can apply. And in the first place it may be observed, that clouds and heat—in short, whatever increases the density or the elasticity of the air in any one place will produce a wind there; for the increased activity of the air thus pressing powerfully on the parts of it that are adjacent will drive them forward, and thus go on in a current till the whole comes to an equality.

In this manner, as a denser air produces a wind on one hand, so will any accident that contributes to lighten the air produce it on the other; for a lighter may be considered as a vacuity into which the neighbouring air will rush; and hence it happens, that when the barometer marks a peculiar lightness in the air it is no wonder that it foretells a storm.

The winds upon large waters are generally more regular than those upon land. The wind at sea generally blows with an even, steady gale; the wind on land puffs by intervals, increasing its strength, and remitting it without any apparent cause. This in a great measure may be owing to the many mountains, towers, or trees that it meets in its way, all contributing either to turn it from its course or interrupt its passage.

The east wind blows more constantly than any other; and for an obvious reason—all other winds are in some measure deviations from it, and may partly owe their

origin thereto. It is generally, likewise, the most powerful—and for the same reason.

There are often double currents of the air: while the wind blows one way we frequently see the clouds move another. This is generally the case before thunder; for it is well known that the thunder-cloud always moves against the wind. The cause of this surprising appearance has hitherto remained a secret. From hence we may conclude that weathercocks only inform us of that current of the air which is near the surface of the earth, but are often erroneous with regard to the upper regions; in fact Derham has often found them erroneous.

Winds are generally more powerful on elevated situations than on the plain, because their progress is interrupted by fewer obstacles. In proportion as we ascend the heights of a mountain, the violence of the weather seems to increase until we have got above the region of storms, where all is usually calm and serene. Sometimes, however, the storms rise even to the tops of the highest mountains—as we learn from those who have been on the Andes, and as we are convinced by the deep snows that crown even the highest.

Winds blowing from the sea are generally moister and more attended with rains than those which blow over extensive tracts of land; for the sea gives off more vapours to the air, and these are rolled forward upon land by the wind's blowing from thence. For this reason our easterly winds that blow from the continent are dry in comparison to those from the surface of the ocean, with which we are surrounded on every quarter.

In general, the winds are more boisterous in spring and autumn than at other seasons; for that being the time of high tides, the sea may communicate a part of its motions to the winds. The sun and moon, also, which then have a greater effect upon the waters, may probably have some influence upon the winds; for, there being a great body of air surrounding the globe, which, if condensed into water, would cover it to the depth of thirty-two feet, it is evident that the sun and moon will, to a proportionable degree, affect the atmosphere, and make it a tide of air. This tide will be scarce perceptible; but without doubt it actually exists, and may contribute to increase the vernal and autumnal storms which are then known to prevail.

Upon narrowing the passage through which the air is driven, both the density and the swiftness of the wind is increased; for as currents of water flow with greater force and rapidity by narrowing their channels, so also will a current of air driven through a contracted space grow more violent and irresistible. Hence we find those dreadful storms that prevail in the defiles of mountains, where the wind, pushing from behind through a narrow channel, at once increases in speed and density, levelling or tearing up every obstacle that rises to obstruct its passage.

Winds reflected from the sides of mountains and towers are often found to be more forceful than those in direct progression. This we frequently perceive near lofty buildings, such as churches or steeples, where winds are generally known to prevail, and are much more powerful than at some distance. The air in this case, by striking against the sides of the building, acquires additional density, and therefore blows with more force.

These differing degrees of density which the air is found to possess sufficiently show that the force of the winds do not depend upon their velocity alone; so that those instruments called "anemometers," which are made to measure the velocity of the wind, will by no means give us certain information of the force of the storm. In order to estimate this with exactness we ought to know its density; which also these are not calculated to discover. For this reason we often see storms with very powerful effects that do not seem to show any great speed; and, on the contrary, we see these wind mea-

surers go round with great swiftness, when scarce any damage has followed from the storm.

Such is the nature and the inconstancy of the irregular winds with which we are best acquainted. But their effects are much more formidable in those climates near the tropics, where they are often found to break in upon the steady course of the trade-winds, and to mark their passage with destruction. With us the tempest is but rarely known, and its ravages are registered as an uncommon calamity; but in the countries that lie between the tropics, and for a good space beyond them, its visits are frequent and its effects anticipated. In these regions the winds vary their terrors; sometimes involving all things in a suffocating heat; sometimes mixing all the elements of fire, air, earth, and water together; sometimes, with a momentary swiftness, passing over the face of the country, and destroying all things in their passage; and sometimes raising whole sandy deserts in one country, to deposit them upon some other. We have little reason, therefore, to envy these climates the luxuriance of their soil or the brightness of their skies. Our own muddy atmosphere, that wraps us round in obscurity, though it fails to gild our prospects with sunshine or our groves with fruitage, nevertheless answers the calls of industry. They may boast of a plentiful but precarious harvest; while with us, the labourer toils in a certain expectation of a moderate but a happy return.

In Egypt—a kingdom so noted for its fertility and the brightness of its atmosphere—during summer, the south winds are so hot that they almost stop respiration; besides which, they are charged with such quantities of sand that they sometimes darken the air as with a thick cloud. These sands are so fine, and driven with such violence, that they penetrate everywhere, even into chests, be they shut ever so closely. If these winds happen to continue for any length of time they produce epidemic diseases, and are often followed by a great mortality. It is also found to rain but very seldom in that country; however, the want of showers is richly compensated by the copiousness of their dews, which greatly tend to promote vegetation.

In Persia, the winter begins in November and continues till March. The cold at that time is intense enough to congeal the water; and snow falls in abundance upon their mountains. During the months of March and April, winds arise that blow with great force, and seem to usher in the heats of summer. These return again in autumn with some violence, without, however, producing any dreadful effects. But during their summer all along the coasts of the Persian Gulph a very dangerous wind prevails which the natives call the "Sameyel," still more dreadful and burning than that of Egypt, and attended with instant and fatal effects. This terrible blast, which was, perhaps, the pestilence of the ancients, instantly kills all those that it involves in its passage. What its malignity consists in none can tell, as none have ever survived its effects to give information. It frequently, as I am told, assumes a visible form, and darts, in a kind of bluish vapour, along the surface of the country. The natives, not only of Persia but of Arabia, talk of its effects with terror; and their poets have not failed to heighten them with the assistance of imagination. They have described it as under the conduct of a minister of vengeance, who governs its terrors, and raises or depresses it as he thinks proper. These deadly winds are also known along the coasts of India, at Necapatan, Masulipatan, and Petapoli. But, luckily for mankind, the shortness of their duration diminishes the injuries that might ensue from their malignity.

The Cape of Good Hope, as well as many islands in the West Indies, are famous for their hurricanes, and that extraordinary kind of cloud which is said to produce them. This cloud, which is the forerunner of a

approaching hurricane, appears, when first seen, like a small black spot on the verge of the horizon, and is called by sailors the "bull's eye," from being seen so minute at a vast distance. All this time a perfect calm reigns over the sea and land, while the cloud grows gradually broader as it approaches. At length, coming to the place where its fury is to fall, it invests the whole horizon with darkness. During all the time of its approach a hollow murmur is heard in the cavities of the mountains; and beasts and animals, sensible of its approach, are seen running over the fields to seek for shelter. Nothing can be more terrible than its violence when it begins. The houses in those countries, which are made of timber the better to resist its fury, bend to the blast like osiers, and again recover their rectitude. The sun which but a moment before blazed with meridian splendour, is totally shut out, and a midnight darkness prevails, except that the air is incessantly illuminated with gleams of lightning, by which one can easily see to read. The rain falls at the same time in torrents; and its descent has been resembled to what pours from the spouts of our houses after a violent shower. These hurricanes are not less offensive to the sense of smell also; and never come without leaving the most noisome stench behind them. If the seamen also lay by their wet clothes for twenty-four hours, they are all found swarming with little white maggots that were brought with the hurricane. Our first mariners when they visited these regions were ignorant of its effects and the signs of its approach; their ships, therefore, were dashed to the bottom at the first onset, and numberless were the wrecks which the hurricane occasioned. But at present, being forewarned of its approach, they strip their masts of all their sails, and thus patiently abide its fury. These hurricanes are common in all the tropical climates. On the coasts of Guinea they have frequently three or four in a day, which thus shut out the heavens for a little space; and when past, leave all again in former splendour. They chiefly prevail on the coast in the intervals of the trade-winds, the approach of which clears the air of its meteors, and gives these mortal showers that little degree of wholesomeness which they possess. They chiefly obtain the during the months of April and May; they are known at Loango from January to April; on the opposite coast of Africa the hurricane season begins in May; and, in general, whenever a trade-wind begins to cease, these irregular tempests are found to exert their fury.

All this is terrible; but there is a tempest known in those climates more formidable than any we have hitherto been describing, which is called by the Spaniards a "Tornado." As the former was seen arriving from one part of the heavens and making a line of destruction, so the winds in this seem to blow from every quarter, and settle upon one destined place with such fury that nothing can resist their vehemence. When they have all met in their central spot, then the whirlwind begins with circular rapidity. The sphere every moment widens as it continues to turn, and catches every object that lies within its attraction. This, also, like the former, is preceded by a flattering calm; the air is everywhere hushed, and the sea is as smooth as polished glass: however, as its effects are more dreadful than those of the ordinary hurricane, the mariner tries all the power of his skill to avoid it; which, if he fails of doing, there is the greatest danger of his going to the bottom. All along the coasts of Guinea, beginning about two degrees north of the line, and so downward, lengthwise, for about a thousand miles and as many broad, the ocean is un-navigable upon account of these tornadoes. In this torpid region there reigns unceasing tornadoes or continual calms; among which, whatever ship is so unhappy as to fall it is totally deprived of all power of escaping. In this dreadful repose of all the elements, the solitary vessel is obliged to continue without a single

breeze to assist the mariner's wishes, except those whirlwinds, which only serve to increase his calamity. At present, therefore, this part of the ocean is totally avoided; and, although they may be much gold along the coasts of that part of Africa to tempt Avarice, yet there is something much more dreadful than the sabled dragon of antiquity to guard the treasure. As the internal parts of that country are totally unknown to travellers from their burning sands and extensive deserts, so here we find a vast tract of ocean lying off its shores equally unvisited by the mariner.

But of all those terrible tempests that deform the face of Nature and repress human presumption, the sandy tempests of Arabia and Africa are the most terrible, and strike the imagination most strongly. To conceive a proper idea of these, we are by no means to suppose them resembling those whirlwinds of dust that we sometimes see scattering in our air, and sprinkling their contents upon our roads or meadows. The sand-storm of Africa exhibits a very different appearance. As the sand of which the whirlwind is composed is excessively fine, and almost resembles the parts of water, its motion entirely resembles that of a fluid; and the whole plain seems to float onward like a slow inundation. The body of sand thus rolling is deep enough to bury houses and palaces in its bosom: travellers who are crossing those extensive deserts perceive its approach at a distance, and in general have time to avoid it or turn out of its way, as it generally extends but to a moderate breadth. However, when it is extremely rapid or very extensive, as sometimes is the case, no swiftness, no art can avail; nothing then remains but to meet death with fortitude, and submit to be buried alive with resignation.

It is happy for us of Britain that we have no such calamity to fear; for from this even some parts of Europe are not entirely free. We have an account given us, in the History of the French Academy, of a miserable town in France that is constantly in danger of being buried under a similar inundation; with which I will take leave to close this chapter. "In the neighbourhood of St. Paul de Leon, in Lower Brittany, there lies a tract of country along the sea-side, which before the year 1666 was inhabited, but now lies deserted, by reason of the sands which cover it, to the height of twenty feet; and which every year advance more and more inland, and gain ground continually. From the time mentioned above, the sand has buried more than six leagues of the country inward; and it is now but half a league from the town of St. Paul; so that in all appearance the inhabitants must be obliged to abandon it entirely. In the country that has been overwhelmed there are still to be seen the tops of some steeples peeping through the sand, and many chimneys that still remain above this sandy ocean. The inhabitants, however, had sufficient time to escape; but being deprived of their little all they had no other resource but begging for their subsistence. This calamity chiefly owes its advancement to a north or an east wind, raising the sand, which is extremely fine, in such great quantities and with such velocity, that M. Deslandes, who gave the account, says, that while he was walking near the place during a moderate breeze of wind, he was obliged from time to time to shake the sand from his clothes and his hat, on which it was lodged in great quantities, and made them too heavy to be easily borne. Still further, when the wind was violent, it drove the sand across a little arm of the sea, into the town of Roscoff, and covered the streets of that place two feet deep; so that they have been obliged to carry it off in carts. It may also be observed, that there are several particles of iron mixed with the sand, which are readily affected by the loadstone. The part of the coast that furnishes these sands is a tract of about four leagues in length, and is upon a level with the sea at high-water. The shore lies in such a manner as to leave its sands subject only to the north and east winds, that bear them

Farther up the shore. It is easy to conceive how the same sand that has at one time been borne a short way inland, may, by some succeeding and stronger blast, be carried up much higher; and thus the whole may continue advancing forward, deluging the plain, and totally destroying its fertility. At the same time the sea, from whence this deluge of sand proceeds, may furnish it in inexhaustible quantities. This unhappy country, thus overwhelmed in so singular a manner, may well justify what the ancients and the moderns have reported concerning those tempests of sand in Africa, that are said to destroy villages, and even armies, in their bosom."

## CHAP. XXI.

### OF METEORS, AND SUCH APPEARANCES AS RESULT FROM A COMBINATION OF THE ELEMENTS.

In proportion as the substances of Nature are more compounded and combined, their appearances become more inexplicable and amazing. The properties of water have been very nearly ascertained. Many of the qualities of air, earth, and fire have been discovered and estimated; but when these come to be united by Nature, they often produce a result which no artificial combinations can imitate; and we stand surprised that, although we are possessed of all those substances which Nature makes use of, she shows herself a much more various operator than the most skilful chymist ever appeared to be. Every cloud that moves and every shower that falls serves to mortify the philosopher's pride, and to show him hidden qualities in air and water that he finds it difficult to explain. Dews, hail, snow, and thunder are not less difficult for being more common. Indeed, when we reflect on the manner in which Nature performs any one of these operations our wonder increases. To see water (which is heavier than air) rising in air, and then falling in a form so very different from that in which it rose; to see the same fluid at one time descending in the form of hail—at another, in that of snow; to see two clouds, by dashing against each other, producing an electrical fire which no watery composition that we know of can effect;—these, I say, serve sufficiently to excite our wonder; and still the more, in proportion as the objects are ever pressing on our curiosity. Much, however, has been written concerning the manner in which Nature operates in these productions—as nothing is so ungrateful to mankind as hopeless ignorance.

And first, with regard to the manner in which water evaporates and rises to form clouds, much has been advanced and many theories devised. All water, say some, has a quantity of air mixed with it; and the heat of the sun darting down, disengages the particles of the air from the grosser fluid: the sun's rays, being reflected back from the water, carry back with them those bubbles of air and water, which, being lighter than the condensed air, will ascend till they meet with a more rarified air; and they will then stand suspended. Experience, however, proves nothing of all this. Particles of air or fire are not thus known to ascend with a thin coat of water; in fact, we know the little particles of steam are solid drops of water. But besides this, water is known to evaporate more powerfully in the severest frost than when the air is moderately warm. Dr. Hamilton, therefore, of the University of Dublin, rejecting this theory, has endeavoured to establish another. According to him, as *aqua fortis* is a menstruum that dissolves iron and keeps it mixed in the fluid—as *aqua regia* is a menstruum that dissolves gold—or as water dissolves salts to a certain quantity,—so air is a menstruum that corrodes and dissolves a certain quantity of water, and keeps it suspended above. But however ingenious this may be, it can hardly be admitted; as we know, by Mariotte's

experiment, that if water and air be enclosed together, instead of the air's acting as a menstruum upon the water, the water will act as a menstruum upon the air, and take it all up. We know, also, that of two bodies that which is most fluid and penetrating is most likely to be the menstruum of the other; but water is more fluid and penetrating than air, and therefore the most likely of the two to be the menstruum. We know that all bodies are more speedily acted upon the more their parts are brought into contact with the menstruum that dissolves them; but water enclosed with compressed air is not the more diminished thereby. In short, we know that cold, which diminishes the force of other menstrooms, is often found to promote evaporation. In this variety of opinion and uncertainty of conjecture, I cannot avoid thinking that a theory of evaporation may be formed upon very simple and obvious principles, and embarrassed, as far as I can conceive, with very few objections.

We know that a repelling power prevails in Nature not less than an attractive one. This repulsion prevails strongly between the body of fire and that of water. If I plunge the end of a red hot bar of iron into a vessel of water, the fluid rises, and large drops of it fly up in all manner of directions, every part bubbling and steaming until the iron be cold. Why may we not for a moment compare the rays of the sun, darted directly upon the surface of the water, to so many bars of red hot iron; each bar, indeed, infinitely small, but not the less powerful? In this case, whenever a ray of fire darts, the water, from its repulsive quality, will be driven on all sides; and, of consequence, as in the case of the bar of iron, a part of it will rise. The parts thus rising, however, will be extremely small; as the ray that darts is extremely so. The assemblage of the rays darting upon the water in this manner will cause it to rise in a light thin steam above the surface; and as the parts of this steam are extremely minute, they will be lighter than air, and consequently float upon it. There is no need for supposing them bubbles of water filled with fire; for any substance, even gold itself, will float on air if its parts be made small enough—or, in other words, if its surface be sufficiently increased. This water, thus disengaged from the general mass, will be farther attenuated and broken by the reflected rays, and, consequently, more adapted for ascending.

From this plain account every appearance in evaporation may be easily deduced. The quantity of heat increases evaporation, because it raises a greater quantity of steam. The quantity of wind increases evaporation; for, by waving the surface to the water, it thus exposes a greater surface to the evaporating rays. A dry frost in some measure assists the quantity of evaporation, as the quantity of rays are found to be no way diminished thereby. Moist weather alone prevents evaporation; for the rays being absorbed, refracted, and broken by the intervening moisture before they arrive at the surface, cannot produce the effect; and the vapour will rise in a small proportion.

Thus far we have accounted for the ascent of vapours; but to account for their falling again is attended with rather more difficulty. We have already observed that the particles of vapour, disengaged from the surface of the water, will be broken and attenuated in their ascent by the reflected, and even the direct, rays that happen to strike upon their minute surfaces. They will therefore continue to ascend till they rise above the operation of the reflected rays, which reaches but to a certain height above the surface of the earth. Being arrived at this region, which is cold for want of reflected heat, they will be condensed, and suspended in the form of clouds. Some vapours that ascend to great heights will be frozen into snow; others, that are condensed lower down, will put on the appearance of a mist, which we find the clouds to be when we ascend among them, as they hang

along the sides of a mountain. These clouds of snow and rain, being blown about by winds, are either entirely scattered and dispersed above, or they are still more condensed by motion, like a snow-ball, that grows more large and solid as it continues to roll. At last, therefore, they will become too weighty for the air which first raised them to sustain; and they will descend with their excess of weight, either in snow or rain. But as they will fall precipitately when they begin to descend, the air in some measure will resist the falling; for, as the descending fluid gathers velocity in its precipitation, the air will increase its resistance to it, and the water will therefore be thus broken into rain—as we see that water which falls from the tops of houses, though it begins in a spout, separates into drops before it has got to the bottom. Were it not for this happy interposition of the air between us and the water falling from a considerable height above us, a drop of rain might fall with dangerous force, and a hailstone might strike us with fatal rapidity.

In this manner evaporation is produced by day; but when the sun goes down, a part of that vapour which his rays had excited, being no longer broken and attenuated by the reflecting rays, it will become heavier than the air, even before it has reached the clouds; and it will therefore fall back in dews, which differ only from rain in descending before they have had time to condense into a visible form.

Hail, the Cartesians say, is a frozen cloud, half melted, and frozen again in its descent. A hoar-frost is but a frozen dew. Lightning we know to be an electrical flash produced by the opposition of two clouds; and thunder to be found proceeding from the same, continued by an echo reverberated among them. It would be to very little purpose to attempt explaining exactly how these wonders are effected: we have as yet but little insight into the manner in which these meteors are found to operate upon each other; and, therefore, we must be contented with a detail rather of their effects than their causes.

In our own gentle climate, where Nature wears the mildest and kindest aspect, every meteor seems to befriend us. With us, rains fall in refreshing showers, to enliven our fields and to paint the landscape with a more vivid beauty. Snows cover the earth to preserve its tender vegetables from the inclemency of the departing winter. The balmy dews descend so imperceptibly as in no way injures the constitution. Even thunder itself is seldom injurious; and it is often wished by the husbandman to clear the air, and to kill numberless insects that are noxious to vegetation. Hail is the most injurious meteor that is known in our climate; but it seldom visits us with violence, and then its fury is but transient.

One of the most dreadful storms we hear of was that at Hertfordshire, in the year 1697. It began by thunder and lightning, which continued for some hours, when suddenly a black cloud came forward, against the wind, and marked its passage with devastation. The hailstones which it poured down, being measured, were found to be many of them fourteen inches round, and consequently as large as a bowling-green ball. Wherever it came every plantation fell before it; it tore up the ground, split great oaks and other trees without number; the fields of rye were cut down as if levelled with a scythe; wheat, oats, and barley suffered the same damage. The inhabitants found but a precarious shelter even in their houses, their tiles and windows being broke by the violence of the hailstones, which, by the force with which they came, seemed to have descended from a great height. The birds in this universal wreck vainly tried to escape by flight; pigeons, crows, and rooks, and many more of the smaller and feebler kinds, were brought down. An unhappy young man, who had not time to take shelter, was killed; one of his eyes was struck out of his head, and his body was all over black with the bruises:

another had just time to escape, but not without the most imminent danger, his body being bruised all over. But what is most extraordinary, all this fell within the compass of a mile.

Mezeray, in his History of France, tells us of a shower of hail much more terrible, which happened in the year 1510, when the French monarch invaded Italy. There was for a time a horrid darkness, thicker than that of midnight, which continued till the terrors of mankind were changed to still more terrible objects, by thunder and lightning breaking the gloom, and bringing on such a shower of hail as no history of human calamities could equal. These hailstones were of a bluish colour; and some of them weighed not less than a hundred pounds. A noisome vapour of sulphur attended the storm. All the birds and beasts of the country were entirely destroyed. Numbers of the human race suffered the same fate. But what is still more extraordinary, the fishes found no protection from their native element, but were equal sufferers in the general calamity.

These, however, are terrors that are seldom exerted in our mild climates. They only serve to mark the page of history with wonder; and stand as admonitions to mankind of the various stores of punishment in the hands of the Deity, which His power can treasure up, and His mercy can suspend.

In the temperate zones, therefore, meteors are rarely found thus terrible; but between the tropics and near the poles they assume very dreadful and various appearances. In those inclement regions where Cold and Heat exert their chief power, meteors seem peculiarly to have fixed their residence. They are seen there in a thousand terrifying forms astonishing to Europeans, yet disregarded by the natives from their frequency. The wonders of air, fire, and water are there combined to produce the most tremendous effects; and to sport with the labours and apprehensions of mankind. Lightnings, that flash without noise; hurricanes, that tear up the earth; clouds, that all at once pour down their contents, and produce an instant deluge; mock suns; northern lights, that illuminate half the hemisphere; circular rainbows; haloes; fleeting balls of fire; clouds reflecting back the images of things on earth, like mirrors; and waterspouts, that burst from the sea to join with the mists that hang immediately above them. These are but a part of the phenomena that are common in those countries, and from many of which our own climate is in a great measure exempted.

The meteors of the torrid zone are different from those that are found near the polar circles; and it may readily be supposed that in those countries where the sun exerts the greatest force in raising vapours of all kinds, there should be the greatest quantity of meteors. Upon the approach of the winter months, as they are called under the line, which usually begin about May, the sky, from a fiery brightness, begins to be overcast, and the whole horizon seems wrapt in a muddy cloud. Mists and vapours still continue to rise; and the air, which so lately before was clear and elastic, now becomes humid, obscure, and stifling: the fogs become so thick, that the light of the sun seems in a manner excluded; nor would its presence be known but for the intense and suffocating heat of its beams, which dart through the gloom, and, instead of dissipating, only serve to increase the mist. After this preparation there follows an almost continual succession of thunder, rain, and tempests. During this dreadful season the streets of cities flow like rivers, and the whole country wears the appearance of an ocean. The inhabitants often make use of this opportunity to lay in a stock of fresh water for the rest of the year—as the same cause which pours down the deluge at one season denies the kindly shower at another. The thunder which attends the fall of these rains is much more terrible than that we are generally acquainted with. With us the flash is seen at some distance, and the noise

shortly after ensues; our thunder generally rolls on one quarter of the sky, and one stroke pursues another. But here it is otherwise; the whole sky seems illuminated with unremitted flashes of lightning; every part of the air seems productive of its own thunders; and every cloud produces its own shock. The strokes come so thick that the inhabitants can scarce mark the intervals, but all is one unremitted roar of elementary confusion. It would seem, however, that the lightning of those countries is not so fatal nor so dangerous as with us; since in this case the torrid zone would be uninhabitable.

When these terrors have ceased—with which, however, the natives are familiar—meteors of another kind begin to make their appearance. The intense beams of the sun, darting upon stagnant waters that generally cover the surface of the country, raise vapours of various kinds. Floating bodies of fire, which assume different names (rather from their accidental forms than from any real difference between them), are seen without surprise. The “draco volans,” or flying dragon, as it is called; the “ignis-fatuus,” or wandering fire; the “fires of St. Helmo,” or the mariner’s light,—are everywhere frequent; and of these we have numberless descriptions. “As I was riding in Jamaica,” says Mr. Barham, “one morning from my habitation, situated about three miles north-west from Jago de la Vega, I saw a ball of fire, appearing to me about the size of a bomb, swiftly falling down with a great blaze. At first I thought it fell into the town; but when I came nearer I saw my people gathered together, a little to the southward, in the Savannah, to whom I rode up to inquire the cause of their meeting. They were admiring, as I found, the ground’s being strangely broken up and ploughed by a ball of fire, which, as they said, fell down there. I observed there were many holes in the ground—one in the middle of the higness of a man’s head, and five or six smaller ones round about of the size of one’s fist, and so deep as not to be fathomed by such implements as were at hand. It was observed, also, that all the green herbage was burnt up near the holes; and there continued a strong smell of sulphur near the place for some time after.”

Ulloa gives an account of one of a similar kind at Quito. “About nine at night,” he says, “a globe of fire appeared to rise from the side of the mountain Pichinca, and so large, that it spread a light over all the part of the city facing that mountain. The house in which I lodged looking that way, I was surprised with an extraordinary light darting through the crevices of the window-shutters. On this appearance, and the bustle of the people in the street, I hastened to the window, and came time enough to see it in the middle of its career, which continued from west to south till I lost sight of it, being intercepted by a mountain which lay between. It was round, and its apparent diameter about a foot. I observed it to rise from the sides of Pichinca; although, to judge from its course, it was behind that mountain where this congeries of inflammable matter was kindled. In the first half of its visible course it emitted a prodigious effulgence, then it began gradually to grow dim; so that, upon its disappearing behind the intervening mountain, its light was very faint.”

Meteors of this kind are very frequently seen between the tropics; but they sometimes also visit the more temperate regions of Europe. We have the description of a very extraordinary one given us by Montanari, that serves to show to what great heights in our atmosphere these vapours are found to ascend. In the year 1676, a great globe of fire was seen at Bononia, in Italy, about three quarters of an hour after sun-set. It passed westward with a most rapid course, at the rate of not less than a hundred and sixty miles in a minute, which is much swifter than the force of a cannon-ball, and at last stood over the Adriatic Sea. In its course it crossed over all Italy; and by computation it could not have been less than thirty-eight miles above the surface of

the earth. In the whole line of its course, wherever it approached, the inhabitants below could distinctly hear it, with a hissing noise resembling that of a firework. Having passed away to sea towards Corsica, it was heard at last to go off with a violent explosion, much louder than that of a cannon; and immediately after another noise was heard, like the rattling of a heavy cart upon a stony pavement—which was probably nothing more than the echo of the former sound. Its magnitude when at Bononia appeared to be twice as long as the moon one way, and as broad the other; so that, considering its height, it could not have been less than a mile long and half a mile broad. From the height at which this was seen, and there being no volcano in that quarter of the world from whence it came, it is more than probable that this terrible globe was kindled on some part of the contrary side of the globe, in those regions of vapours which we have been just describing; and thus, rising above the air, and passing in a course opposite to that of the earth’s motion, in this manner it acquired its amazing rapidity.

To these meteors, common enough southward, we will add one more of a very uncommon kind, which was seen by Ulloa at Quito, in Peru—the beauty of which will in some measure serve to relieve us, after the description of those hideous ones preceding. “At day-break,” he observes, “the whole mountain of Pambamarca, where we then resided, was encompassed with very thick clouds, which the rising of the sun dispersed so far as to leave only some vapours too fine to be seen. On the side opposite to the rising sun, and about ten fathoms distant from the place where we were standing, we saw, as in a looking-glass, each his own image—the head being, as it were, the centre of three circular rainbows, one without the other, and just near enough to each other as that the colours of the internal verged upon those more external; while round all was a circle of white, but with a greater space between. In this manner these circles were erected like a mirror before us; and as we moved, they moved in disposition and order. But what is most remarkable, though we were six in number, every one saw the phenomenon with regard to himself, and not that relating to others. The diameter of the arches gradually altered as the sun rose above the horizon; and the whole, after continuing a long time, insensibly faded away. In the beginning, the diameter of the inward iris, taken from its last colour, was about five degrees and a half; and that of the white arch, which surrounded the rest, was not less than sixty-seven degrees. At the beginning of the phenomenon the arches seemed of an oval or elliptical figure, like the disk of the sun; and afterwards became perfectly circular. Each of these was of a red colour, bordered with orange; and the last bordered by a bright yellow, which altered into a straw-colour, and this turned to a green; but in all, the external colour remained red.” Such is the description of one of the most beautiful illusions that has ever been seen in Nature. This alone seems to have combined all the splendours of optics in one view. To understand the manner, therefore, how this phenomenon was produced would require a perfect knowledge of optics; which it is not our present province to enter upon. It will be sufficient, therefore, only to observe, that all these appearances arise from the density of the cloud, together with its uncommon and peculiar situation with respect to the spectator and the sun. It may be observed, that but one of these three rainbows was real, the rest being only reflections thereof. It may also be observed that whenever the spectator stands between the sun and a cloud of falling rain, a rainbow is seen, which is nothing more than a reflection of the different coloured rays of light from the bosom of the cloud. If, for instance, we take a glass globe filled with water, and hand it up before us opposite the sun, in many situations it will appear transparent; but if it is raised higher, or

sideways, to an angle of forty-five degrees, it will at first appear red; a very little higher, yellow; then green, then blue, then violet colour; in short, it will assume successively all the colours of the rainbow; but, if raised higher, still it will become transparent again. A falling shower may be considered as an infinite number of these little transparent globes, assuming different colours by being placed at the proper heights. The rest of the shower will appear transparent, and no part of it will seem coloured—but such as are angles of forty-five degrees from the eye, forty-five degrees upward, forty-five degrees on each side, forty-five degrees downward, did not the plane of the earth prevent us. We therefore see only an arch of the rainbow, the lower part being cut off from our sight by the earth's interposition. However, upon the tops of very high mountains circular rainbows are seen, because we can see to an angle of forty-five degrees downward, as well as upward or sideways, and therefore we take in the rainbow's complete circle.

In those forlorn regions round the poles, the meteors, though of another kind, are not less numerous and alarming. When the winter begins, and the cold prepares to set in, the same misty appearance which is produced in the southern climates by the heat is there produced by the contrary extreme. The sea smokes like an oven, and a fog arises, which mariners call the "frost-smoke." This cutting mist commonly raises blisters on several parts of the body; and as soon as it is wafted to some colder part of the atmosphere it freezes into little icy particles, which are driven by the wind, and create such an intense cold on land that the limbs of the inhabitants are sometimes frozen, and drop off.

There, also, haloes, or luminous circles round the moon, are oftener seen than in any other part of the earth, being formed by the frost-smoke—although the air in other respects seems to be clear. A lunar rainbow, also, is often seen there, though rather different from that common to us, as it appears of a pale white striped with grey. In these countries, also, the aurora-borealis streams with peculiar lustre and variety of colours. In Greenland it generally arises in the east, and darts its sportive fires in variegated beauty over the whole horizon. Its appearance is almost constant in winter; and at those seasons when the sun departs, to return no more for half a year, this meteor kindly rises to supply its beams, and affords sufficient light for all the purposes of existence. However, in the very midst of their tedious night the inhabitants are not entirely forsaken. The tops of the mountains are often seen painted with the red rays of the sun; and the poor Greenlanders from thence begin to date his chronology. It would appear whimsical to read a Greenland calendar, in which we might be told—That one of their chiefs, having lived forty days, died at last of a good old age; and that his widow continued for half a day to deplore his loss with great fidelity, and then—admitted a second husband.

The meteors of the day in these countries are not less extraordinary than those of the night. Mock suns are often reflected upon an opposite cloud; and the ignorant spectator fancies that there are often three or four real suns in the firmament at the same time. In this splendid appearance the real sun is always readily known by its superior brightness, every reflection being seen with diminished splendour. The solar rainbow there is often seen different from ours: instead of a pleasing variety of colours, it appears of a pale white, edged with a stripe of dusky yellow—the whole being reflected from the bosom of a frozen cloud.

But of all the meteors which mock the imagination with an appearance of reality, those strange illusions that are seen there in fine serene weather are the most extraordinary and entertaining. "Nothing," says Krantz, "ever surprised me more than, on a fine warm summer's day, to perceive the islands that lie four leagues west

of our shore putting on a form quite different from what they are known to have. As I stood gazing upon them, they appeared at first infinitely greater than what they naturally are, and seemed as if I viewed them through a large magnifying-glass. They were thus not only made larger, but brought nearer to me. I plainly descried every stone upon the land, and all the furrows filled with ice, as if I stood close by. When this illusion had lasted for a while the prospect seemed to break up, and a new scene of wonder to present itself. The islands seemed to travel to the shore, and represented a wood, or a tall cut hedge. The scene then shifted, and showed the appearance of all sorts of curious figures, as ships with sails, streamers, and flags; antique elevated castles, with decayed turrets; and a thousand forms for which fancy found a resemblance in Nature. When the eye had been satisfied with gazing, the whole groupe of riches seemed to rise in air, and at length vanish into nothing. At such times the weather is quite serene and clear; but, compressed with such subtle vapours as it is in very hot weather, and these appearing between the object, give it all that variety of appearances which glasses of different refrangibilities would have done." Mr. Krantz observes, that commonly a couple of hours afterwards a gentle west wind and a visible mist follows, which puts an end to this "*lusus naturæ*."

It were easy to swell this catalogue of meteors with the names of many others, both in our own climate and in other parts of the world—such as falling stars, which are thought to be no more than unctuous vapours raised from the earth to small heights, and continuing to shine till that matter which first raised and supported them being burnt out, they fall back again to the earth with extinguished flame; burning spears, which are a peculiar kind of aurora-borealis; bloody rains, which are said to be the excrements of an insect that at that time has been raised into the air; showers of stones, fishes, and ivy-berries—at first, no doubt, raised into the air by tempests in one country, and falling at some considerable distance, in the manner of rain, to astonish another. But omitting these—of which we know little more than what is thus briefly mentioned—I will conclude this chapter with the description of a water-spout—a most surprising phenomenon, not less dreadful to mariners than astonishing to the observer of Nature.

These spouts are seen very commonly in the tropical seas, and sometimes in our own. Those seen by Tournefort in the Mediterranean he has described as follows:—"The first of these," says this great botanist, "that we saw was about a musket-shot from our ship. There we perceived the water began to boil, and to rise about a foot above its level. The water was agitated and whitish; and above its surface there seemed to stand a smoke, such as might be imagined to come from wet straw before it begins to blaze. It made a sort of murmuring sound, like that of a torrent heard at a distance, mixed with a hissing noise like that of a serpent; shortly after we perceived a column of this smoke rise up to the clouds, at the same time whirling about with great rapidity. It appeared to be as thick as one's finger, and the former sound still continued. When this disappeared, after lasting for about eight minutes, upon turning to the opposite quarter of the sky we perceived another, which began in the manner of the former; presently after a third appeared in the west; and instantly beside it still another arose. The most distant of these three could not be above a musket-shot from the ship. They all appeared like so many heaps of wet straw set on fire, that continued to smoke, and to make the same noise as before. We soon after perceived each, with its respective canal mounting up in the clouds, and spreading where it touched—the cloud, like the mouth of a trumpet, making a figure, to express it intelligibly, as if the tail of an animal were pulled at one end by a weight. These canals were of a whitish colour, and so tinged, as I sup-

poor, by the water which was contained in them; for previous to this they were apparently empty, and of the colour of transparent glass. These canals were not straight, but bent in some parts, and far from being perpendicular, but rising in their clouds with a very inclined ascent. But what is the most particular, the cloud to which one of them was pointed happening to be driven by the wind, the spout still continued to follow its motion without being broken; and, passing behind one of the others, the saucers crossed each other in the form of St. Andrew's cross. In the beginning they were all about as thick as one's finger, except at the top, where they were broader; and two of them disappeared; but shortly after the last of the three increased considerably, and its canal, which was at first so small, soon became as thick as a man's arm, then as his leg, and at last thicker than his whole body. We saw distinctly through this transparent body the water, which rose up with a kind of spiral motion; and it sometimes diminished a little of its thickness, and again resumed the same; sometimes widening at top, and sometimes at bottom; exactly resembling a gut filled with water, pressed with the fingers to make the fluid rise or fall; and I am well convinced that this alteration in the spout was caused by the wind, which pressed the cloud and impelled it to give up its contents. After some time its bulk was so diminished as to be no thicker than a man's arm again; and thus, swelling and diminishing, it at last became very small. In the end, I observed the sea which was raised about it to resume its level by degrees, and the end of the canal that touched it to become as small as if it had been tied round with a cord; and this continued till the light, striking through the cloud, took away the view. I still, however, continued to look, expecting that its parts would join again, as I had before seen in one of the others, in which the spout was more than once broken, and yet again came together; but I was disappointed, for the spout appeared no more."

Many have been the solutions offered for this surprising appearance. Mr. Buffon supposes the spout here described to proceed from the operation of fire beneath the bed of the sea, as the waters at the surface are thus seen agitated. However, the solution of Dr. Stuart is not divested of probability, who thinks it may be accounted for by suction, as in the application of a cupping-glass to the skin.

Wherever spouts of this kind are seen they are extremely dreaded by mariners; for if they happen to fall upon a ship they most commonly dash it to the bottom. But if the ship be large enough to sustain the deluge, they are at least sure to destroy its sails and rigging, and render it unfit for sailing. It is said that vessels of any force usually fire their guns at them, loaded with a bar of iron; and, if so happy as to hit them, the water is instantly seen to fall from them with a dreadful noise, though without any further mischief.

I am at a loss whether we ought to reckon these spouts, called "typhons" (which are sometimes seen on land), of the same kind with those so often described by mariners at sea, as they seem to differ in several respects. That, for instance, observed at Hatfield, in Yorkshire, in 1687, as it is described by the person who saw it, seems rather to have been a whirlwind than a water-spout. The season in which it appeared was very dry, the weather extremely hot, and the air very cloudy. After the wind had blown for some time with considerable force, and condensed the black clouds one upon another, a great whirling of the air ensued; upon which the centre of the clouds every now and then darted down in the shape of a thick, long, black pipe, in which the relator could distinctly see a motion, like that of a screw, continually screwing up to itself, as it were, whatever it happened to touch. In its progress it moved slowly over a grove of young trees, which it violently bent in a circular motion. Going forward to a barn, it in less

than a minute stript it of all the thatch, and filled the whole air with the same. As it came nearer the relator, he perceived that its blackness proceeded from a gyration of the clouds, by contrary winds meeting in a point or centre; and where the greatest force was exerted, there darting down, like an Archimedes' screw, to suck up all that came in its way. Another which he saw some time after was attended with still more terrible effects—levelling or tearing up great oak trees, catching up the birds in its vortex, and dashing them against the ground. In this manner it proceeded, with an audible whirling noise like that of a mill; and at length dissolved, after having done much mischief.

But we must still continue to suspend our assent as to the nature of even these land-spouts, since they have been sometimes found to drop in a great column of water at once upon the earth, and produce an instantaneous inundation, which could not readily have happened had they been caused by the gyration of a whirlwind only. Indeed, every conjectures regarding these meteors seems to me entirely unsatisfactory. They sometimes appear in the calmest weather at sea, of which I have been an eye-witness; and therefore these are not caused by a whirlwind. They are always capped by a cloud; and therefore are not likely to proceed from fires at the bottom. They change place; and therefore suction seems impracticable. In short, we still want facts upon which to build a rational theory; and instead of knowledge we must be contented with admiration. To be well acquainted with the appearances of Nature, even though we are ignorant of their causes, often constitutes the most useful wisdom.

## CHAP. XXII.

### THE CONCLUSION.

Having thus gone through a particular description of the earth, let us now pause for a moment to contemplate the great picture before us. The universe may be considered as the palace in which the Deity resides; and this earth is one of its apartments. In this, all the meaner races of Animated Nature mechanically obey Him; and stand ready to execute His commands without hesitation. Man alone is found refractory; he is the only being endued with a power of contradicting these mandates. The Deity was pleased to exert superior power in creating him a superior being—a being endued with a choice of good and evil, and capable, in some measure, of co-operating with his own intentions. Man, therefore, may be considered as a limited creature endued with powers imitative of those residing in the Deity. He is thrown into a world that stands in need of his help, and has been granted a power of producing harmony from partial confusion.

If, therefore, we consider the earth as allotted for our habitation, we shall find that much has been given us to enjoy and much to amend; that we have ample reasons for our gratitude, and still more for our industry. In those great outlines of Nature to which Art cannot reach, and where our greatest efforts must have been ineffectual, God himself has finished these with amazing grandeur and beauty. Our beneficent Father has considered these parts of Nature as peculiarly His own—as parts which no creature could have skill or strength to amend; and therefore made them incapable of alteration or of more perfect regularity. The heavens and the firmament show the wisdom and the glory of the Workman. Astronomers, who are best skilled in the symmetry of systems, can find nothing there that they can alter for the better. God made these perfect, because no subordinate being could correct their defects.

When, therefore, we survey Nature on this side,

nothing can be more splendid, more correct, or amazing. We therefore behold a Deity residing in the midst of an universe, infinitely extended every way, animating all, and cheering the vacuity with His presence! We behold an immense and shapeless mass of matter formed into worlds by His power, and dispersed at intervals to which even the imagination cannot travel! In this great theatre of His glory, a thousand suns like our own animate their respective systems, appearing and vanishing at Divine command. We behold our own bright luminary fixed in the centre of its system, wheeling its planets in times proportioned to their distances, and at once dispensing light, heat, and action. The earth also is seen with its twofold motion—producing by the one the change of seasons, and by the other the grateful vicissitudes of day and night. With what silent magnificence is all this performed! With what seeming ease! The works of Art are exerted with interrupted force, and their noisy progress discovers the obstructions they receive; but the earth, with a silent, steady rotation, successively presents every part of its bosom to the sun—at once imbibing nourishment and light from that parent of vegetation and fertility.

But not only provisions of heat and light are thus supplied, but its whole surface is covered with a transparent atmosphere that turns with its motion, and guards it from external injury. The rays of the sun are thus broken into a genial warmth; and, while the surface is assisted, a gentle heat is produced in the bowels of the earth which contributes to cover it with verdure. Waters, also, are supplied in healthful abundance, to support life and assist vegetation. Mountains arise to diversify the prospect and give a current to the stream. Seas extend from one continent to the other, replenished with animals that may be turned to human support; and also serving to enrich the earth with a sufficiency of vapour. Breezes fly along the surface of the fields to promote health and vegetation. The coolness of the

evening invites to rest; and the freshness of the morning renews for labour.

Such are the delights of the habitation that has been assigned to man! Without any one of these he must have been wretched; and none of these could his own industry have supplied. But while many of his wants are thus kindly furnished on the one hand, there are numberless inconveniences to excite his industry on the other. This habitation, though provided with all the conveniences of air, pasturage, and water, is but a desert place without human cultivation. The lowest animal finds more conveniences in the wilds of Nature than he who boasts himself their lord. The whirlwind, the inundation, and all the asperities of the air, are peculiarly terrible to man, who knows their consequences, and, at a distance, dreads their approach. The earth itself where human art has not pervaded puts on a frightful gloomy appearance. The forests are dark and tangled; the meadows overgrown with rank weeds; and the brooks stray without a determined channel. Nature, that has been kind to every lower order of beings, has been quite neglectful with regard to him; to the savage, uncontriving man, the earth is an abode of desolation, where his shelter is insufficient and his food precarious.

A world thus furnished with advantages on one side and inconveniences on the other is the proper abode of Reason—is the fittest to exercise the industry of a free and a thinking creature. These evils, which Art can remedy and Prescience guard against, are a proper call for the exertion of his faculties; and they tend still more to assimilate him to his Creator. God beholds with pleasure that being whom He hath made converting the wretchedness of his natural situation into a theatre of triumph; bringing all the headlong tribes of Nature into subjection to his will; and producing that order and uniformity upon earth of which His own heavenly fabric is so bright an example.

## PART II.

---

# OF ANIMALS.

### CHAP. I.

#### A COMPARISON OF ANIMALS WITH THE INFERIOR RANKS OF CREATION.

HAVING given an account of the earth in general, and the advantages and inconveniences with which it abounds, we now come to consider it more minutely. Having described the habitation, we are naturally led to inquire after the inhabitants. Amidst the infinitely different productions which the earth offers, and with which it is everywhere covered, animals hold the first rank—as well because of the finer formation of their parts as of their superior power. The vegetable—which is fixed to one spot, and obliged to wait for its accidental supplies of nourishment—may be considered as the prisoner of Nature. Unable to correct the disadvantages of its situation, or to shield itself from the dangers that surround it, every object that has motion may be its destroyer.

But animals are endowed with powers of motion and defence. The greatest part are capable, by changing place, of commanding Nature, and of thus obliging her to furnish that nourishment which is most agreeable to their state. Those few that are fixed on one spot, even in this seemingly helpless situation, are nevertheless protected from external injury by a hard shelly covering, which they often can close at pleasure, and thus defend themselves from every assault. And here, I think, we may draw the line between the animal and vegetable kingdoms. Every animal, by some means or other, finds protection from injury—either from its force or courage, its swiftness or cunning. Some are protected by hiding in convenient places, and others by taking refuge in a hard shell. But vegetables are totally unprotected; they are exposed to every assailant, and are patiently submissive in every attack. In a word, an animal is an organized being that is in some measure provided for its own security; a vegetable is destitute of every protection.

But though it is very easy without the help of definitions to distinguish a plant from an animal, yet both possess many properties so much alike, that the two kingdoms, as they are called, seem mixed with each other. Hence, it frequently puzzles the naturalist to tell exactly where animal life begins and vegetative terminates; nor indeed is it easy to resolve whether some objects offered to view be of the lowest of the animal or the highest of the vegetable race. The sensitive plant, which moves at the touch, seems to have as much perception as the fresh-water polypus, which is possessed of a still lower share of motion. Besides, the sensitive plant will not reproduce upon cutting in pieces, which

the polypus is known to do; so that the vegetable production seems to have the superiority. But, notwithstanding this, the polypus hunts for its food as most other animals do. It changes its situation; and therefore possesses a power of choosing its food or retreating from danger. Still, therefore, the animal kingdom is far above the vegetable; and its lowest denizen is possessed of very great privileges when compared with the plants with which it is often surrounded.

However, both classes have many resemblances, by which they are raised above the unorganized and inert masses of Nature. Minerals are mere inactive, insensible bodies, entirely motionless of themselves, and waiting some external force to alter their forms or their properties. But it is otherwise with animals and vegetables; these are endued with life and vigour; they have their state of improvement and decay; they are capable of reproducing their kinds; they grow from seeds in some, and from cuttings in others; they seem all possessed of sensation, in a greater or less degree; they both have their enmities and affections; and as some animals are, by nature, impelled to violence, so some plants are found to exterminate all others, and make a wilderness of the places around them. As the lion makes a desert of the forest where it resides, thus no other plant will grow under the shade of the machinel-tree. Thus, also, that plant, in the West-Indies called "caraguata," clings round whatever tree it happens to approach: there it quickly gains the ascendant; and, loading the tree with a verdure not its own, keeps away that nourishment designed to feed the trunk, and at last entirely destroys its supporter. As all animals are ultimately supported upon vegetables, so vegetables are greatly propagated by being made a part of animal food. Birds distribute the seeds wherever they fly, and quadrupeds prune them into greater luxuriance. By these means the quantity of food in a state of nature is kept equal to the number of the consumers; and—lest some of the weaker ranks of animals should find nothing for their support, but all the provisions be devoured by the strong—different vegetables are appropriated to different appetites. If, transgressing this rule, the stronger ranks should invade the rights of the weak, and, breaking through all regard to appetite, should make an indiscriminate use of every vegetable, Nature then punishes the transgression, and poison marks the crime as capital.

If again we compare vegetables and animals with respect to the places where they are found, we shall find them bearing a still stronger similitude. The vegetables that grow in a dry and sunny soil are strong and vigorous, though not luxuriant; so also are the animals of such a climate. Those, on the contrary, that are the joint product of heat and moisture are luxuriant and

tender: and the animals assimilating to the vegetable food, on which they ultimately subsist, are much larger in such places than in others. Thus, in the internal parts of South America and Africa, where the sun usually scorches all above, while inundations cover all below, the insects, reptiles, and other animals grow to a prodigious size: the earth-worm of America is often a yard in length, and as thick as a walking-cane; the boiguacu, which is the largest of the serpent kind, is sometimes forty feet in length; the bats in those countries are as big as a rabbit; the toads are bigger than a duck, and their spiders are as large as a sparrow. On the contrary, in the cold frozen regions of the north, where vegetable nature is stunted of its growth, the few animals in those climates partake of the diminution; all the wild animals, except the bear, are much smaller than in milder countries; and such of the domestic kinds as are carried thither quickly degenerate, and grow less. Their very insects are of the minute kinds, their bees and spiders being not half so large as those in the temperate zone.

The similitude between vegetables and animals is no where more obvious than in those that belong to the ocean, where the nature of one is admirably adapted to the necessities of the other. This element it is well known has its vegetables, and its insects that feed upon them in great abundance. Over many tracts of the sea a weed is seen floating, which covers the surface, and gives the resemblance of a green and extensive meadow. On the under side of these unstable plants millions of little animals are found, adapted to their situation. For as their ground, if I may so express it, lies over their heads, their feet are placed upon their backs; and as land animals have their legs below their bodies, these have them above. On land, also, most animals are furnished with eyes to see their food; but at sea, almost all the reptile kinds are without eyes, which might only give them prospects of danger at a time when unprovided with the means of escaping it.

Thus, in all places we perceive an obvious similitude between the animals and the vegetables of every region. In general, however, the most perfect races have the least similitude to the vegetable productions on which they are ultimately fed; while, on the contrary, the meaner the animal the more local it is found to be, and the more it is influenced by the varieties of the soil where it resides. Many of the more humble reptile kinds are not only confined to one country, but also to a plant—nay, even to a leaf. Upon that they subsist—increase with its vegetation, and seem to decay as it declines. They are merely the circumscribed inhabitants of a single vegetable; take them from that and they instantly die—being entirely assimilated to the plant they feed on, assuming its colour, and even its medicinal properties. For this reason there are infinite numbers of the meaner animals that we have never an opportunity of seeing in this part of the world; they are incapable of living separate from their kindred vegetables, which grow only in a certain climate.

Such animals as are formed more perfect lead a life of less dependence; and some kinds are found to subsist in many parts of the world at the same time. But of all the races of Animated Nature, man is the least affected by the soil where he resides, and least influenced by the variations of vegetable sustenance; equally unaffected by the luxuriance of the warm climates, or the sterility of the poles, he has spread his habitations over the whole earth, and finds subsistence as well amidst the ice of the north as the burning deserts under the line. All creatures of an inferior nature, as has been said, have peculiar propensities to peculiar climates; they are circumscribed to zones, and confined to territories where their proper food is found in the greatest abundance; but man may be called the animal of every climate, and suffers but very gradual alterations from the nature of any situation.

As to animals of a meaner rank, whom man compels to attend him in the migrations, these being obliged to live in a kind of constraint and upon vegetable food, often different from that of their native soil, they very soon alter their natures with the nature of their nourishment, assimilate to the vegetables upon which they are fed, and thus assume very different habits as well as appearances. Thus, man, unaffected himself, alters and directs the nature of other animals at his pleasure, increases their strength for his delight, or their patience for his necessities.

This power of altering the appearance of things seems to have been given him for very wise purposes. The Deity, when He made the earth, was willing to give His favoured creature many opponents, that might at once exercise his virtues, and call forth his latent abilities. Hence we find, in those wide uncultivated wildernesses—where man, in his savage state, owns inferior strength, and the beasts claim divided dominion—that the whole forest swarms with noxious animals and vegetables; animals, as yet undescribed, and vegetables which want a name. In those recesses Nature seems rather lavish than magnificent in bestowing life. The trees are usually of the largest kinds, covered round with parasite plants, and interwoven at the tops with each other. The boughs, both above and below, are peopled with various generations, some of which have never been upon the ground, and others have never stirred from the branches on which they were produced. In this manner millions of minute and loathsome creatures pursue a round of uninterrupted existence, and enjoy a life scarce superior to vegetation. At the same time, the vegetables in those places are of the larger kinds, while the animal race is of the smaller: but man has altered this disposition of Nature—having, in a great measure, levelled the extensive forests, cultivated the softer and finer vegetables, destroyed the numberless tribes of minute and noxious animals, and taken every method to increase a numerous breed of the larger kinds. He thus has exercised a severe control; unpeopled Nature, to embellish it; and diminished the size of the vegetable in order to improve that of the animal kingdom.

To subdue the earth to his own use was, and ought to be, the aim of man; which was only to be done by increasing the number of plants and diminishing that of animals: to multiply existence was that alone of the Deity. For this reason, we find in a state of nature that animal life is increased to the greatest quantity possible; and we can scarce form a system that could add to its numbers. First, plants or trees are provided by Nature of the largest kinds; and consequently the nourishing surface is thus extended. In the second place, there are animals peculiar to every part of the vegetable, so that no part of it is lost. But the greatest possible increase of life would still be deficient were there not other animals that lived upon animals; and these are themselves in turn food for some other greater and stronger set of creatures. Were all animals to live upon vegetables alone, thousands would be extinct that now have existence, as the quantity of their provision would shortly fail. But, as things are wisely constituted, one animal now supports another; and thus all take up less room than they would by living on the same food; as, to make use of a similar instance, a greater number of people may be crowded into the same space if each is made to bear his fellow upon his shoulders.

To diminish the number of animals and increase that of vegetables has been the general scope of human industry; and if we compare the utility of the kinds, with respect to man, we shall find, that of the vast variety in the animal kingdom but very few are serviceable to him; and in the vegetable but very few are entirely noxious. How small a part of the insect tribes, for instance, are beneficial to mankind, and what numbers are injurious! In some countries they almost darken the air: a candle

cannot be lighted without their instantly flying upon it, and putting out the flame. The closest recesses are no safeguard from their annoyance; and the most beautiful landscapes of Nature only serve to invite their rapacity. As these are injurious from their multitudes, so most of the larger kinds are equally dreadful to him from their courage and ferocity. In the most uncultivated parts of the forest these maintain an undisputed empire; and man invades their retreats with fear and dread. These are terrible; and there are still more that are utterly useless to him which serve to take up the room that more beneficial creatures might possess, and incommode him rather with their numbers than their enmities. Thus, in a catalogue of land animals that amounts to more than twenty thousand, we can scarcely reckon up a hundred that are any way useful to him—the rest being either all his open or his secret enemies, immediately attacking him in person, or intruding upon that food he has appropriated to himself. Vegetables, on the contrary, though existing in great variety, are but few of them noxious. The most deadly poisons are often of great use in medicine; and even those plants that only seem to cumber the ground serve for food to that race of animals which he has taken into friendship or protection. The smaller tribes of vegetables, in particular, are cultivated as contributing either to his necessities or amusement; so that vegetable life is as much promoted by human industry as animal life is controlled and diminished.

Hence, it was not without a long struggle and various combinations of experience and art that man acquired his present dominion. Almost every good that he possesses was the result of the contest; for every day he was contending he was growing more wise; and patience and fortitude were the fruits of his industry.

From hence, also, we see the necessity of some animals living upon each other, to fill up the plan of Providence, and we may consequently infer the expediency of man's living upon all. Both animals and vegetables seem equally fitted to his appetites; and, were any religious or moral motives to restrain him from taking away life, upon any account, he would only thus give existence to a variety of beings made to prey upon each other, and, instead of preventing, multiply mutual destruction.

## CHAP. II.

### OF THE GENERATION OF ANIMALS.

Before we survey animals in their state of maturity, and performing the functions adapted to their respective natures, method requires that we should consider them in the more early periods of their existence. There has been a time when the proudest and the noblest animal was a partaker of the same imbecility with the meanest reptile; and, while yet a candidate for existence, equally helpless and contemptible. In their incipient state all are upon a footing—the insect and the philosopher being equally insensible, clogged with matter, and unconscious of existence. Where, then, are we to begin with the history of those beings that make such a distinguished figure in the creation? Or, where lie those peculiar characters in the parts that go to make up Animated Nature—that mark one animal as destined to creep in the dust, and another to glitter on the throne?

This has been a subject that has employed the curiosity of all ages, and the philosophers of every age have attempted the solution. In tracing Nature to her most hidden recesses, she becomes too minute or obscure for our inspection; so that we find it impossible to mark her first differences, to discover the point where animal life begins, or the cause that conduces to set it in motion.

We know little more than that the greatest number of animals require the concurrence of a male and female to reproduce their kind; and that these, distinctly and invariably, are found to beget creatures of their own species. Curiosity has, therefore, been active in trying to discover the immediate result of this union; how far either sex contributes to the bestowing animal life, and whether it be to the male or female that we are most indebted for the privilege of our existence.

Hippocrates has supposed that fecundity proceeded from the mixture of the seminal liquor of both sexes, each of which equally contribute to the formation of the incipient animal. Aristotle, on the other hand, would have the seminal liquor in the male alone to contribute to this purpose, while the female supplied the proper nourishment for its support. Such were the opinions of these Fathers of Philosophers; and these continued to be adopted by the naturalists and schoolmen of succeeding ages with blind veneration. At length Steno and Harvey, taking anatomy for their guide, gave mankind a nearer view of Nature just advancing into animation. These perceived, in all such animals as produced their young alive, two glandular bodies near the womb, resembling that ovary or cluster of small eggs which is found in fowls; and, from the analogy between both, they gave these also the name of ovaria. These, as they resembled eggs, they naturally concluded had the same offices; and therefore they were induced to think that all animals, of what kind soever, were produced from eggs. At first, however, there was some altercation raised against this system; for, as these ovaria were separated from the womb, it was objected that they could not be any way instrumental in replenishing that organ, with which they did not communicate. But upon more minute inspection, Fallopius, the anatomist, perceived two tubular vessels depending from the womb, which, like the horns of a snail, had a power of erecting themselves, of embracing the ovaria, and of receiving the eggs, in order to be fecundated by the seminal liquor. This discovery seemed for a long time after to fix the opinions of philosophers. The doctrine of Hippocrates was re-established, and the chief business of generation was ascribed to the female. This was for a long time the established opinion of the schools; but Leuwenhoeck once more shook the whole system, and produced a new schism among the lovers of speculation. Upon examining the seminal liquor of a great variety of male animals with microscopes, which helped his sight more than that of any of his successors, he perceived therein infinite numbers of little living creatures, like tadpoles, very brisk, and floating in the fluid with a seeming voluntary motion. Each of these, therefore, was thought to be the rudiments of an animal similar to that from which it was produced; and this only required a reception from the female, together with proper nourishment, to complete its growth. The business of generation was now, therefore, given back to the male a second time by many; while others suspended their assent, and chose rather to confess ignorance than to embrace error.

In this manner has the dispute continued for several ages, some accidental discovery serving at intervals to renew the debate and revive curiosity. It was a subject where speculation could find much room to display itself; and Mr. Buffon, who loved to speculate, would not omit such an opportunity of giving scope to his propensity. According to this most pleasing of all naturalists, the microscope discovers that the seminal liquor, not only of males but of females also, abounds in these moving little animals, which have been mentioned above, and that they appear equally brisk in either fluid. These he takes not to be real animals, but organized particles, which, being simple, cannot be said to be organized themselves, but go to the composition of all organized bodies whatsoever. In the same manner as a

tooth in the wheel of a watch cannot be called either the wheel or the watch, and yet contributes to the sum of the machine. These organical particles are, according to him, diffused throughout all Nature, and to be found not only in the seminal liquor, but in most other fluids in the parts of vegetables, and all parts of Animated Nature. As they happen, therefore, to be differently applied, they serve to constitute a part of the animal or the vegetable whose growth they serve to increase, while the superfluity is thrown off in the seminal liquor of both sexes for the reproduction of other animals or vegetables of the same species. These particles assume different figures, according to the receptacle into which they enter; falling into the womb they unite into a fœtus; beneath the bark of a tree they pullulate into branches; and, in short, the same particles that first formed the animal into the womb contribute to increase its growth when brought forth.

To this system it has been objected, that it is impossible to conceive organical substances without being organized; and that, if divested of organization themselves, they could never make an organized body, as an infinity of circles could never make a triangle. It has also been objected, that it is more difficult to conceive the transformation of these organical particles than even that of the animal whose growth we are inquiring after; and this system, therefore, attempts to explain one obscure thing by another still more obscure.

But an objection still stronger than these has been advanced by an ingenious countryman of our own, who asserts that these little animals, which thus appear swimming and sporting in almost every fluid we examine with a microscope, are not real living particles, but some of the more opaque parts of the fluid, that are thus increased in size, and seem to have a much greater motion than they have in reality—for, the motion being magnified with the object, the smallest degree of it will seem very considerable; and a being almost at rest may, by these means, be apparently put into violent action. Thus, for instance, if we look upon the sails of a wind-mill moving at a distance, they appear to go very slow; but if we approach them, and thus magnify their bulk to our eye, they go round with great rapidity. A microscope in the same manner serves to bring our eye close to the object, and thus to enlarge it: and not only increase the magnitude of its parts, but of its motion. Hence, therefore, it would follow, that these organical particles that are said to constitute the bulk of living nature are but mere optical illusions; and the system founded on them must, like them, be illusive.

These and many other objections have been made to this system, which, instead of enlightening the mind, serve only to show that too close a pursuit of Nature very often leads to uncertainty. Happily, however, for mankind, the most intricate inquiries are generally the most useless. Instead, therefore, of balancing accounts between the sexes, and attempting to ascertain to which the business of generation most properly belongs, it will be more instructive as well as amusing to begin with Animal Nature, from its earliest retirements and evanescent outlines, and pursue the incipient creature through all its changes in the womb till it arrives into open day.

The usual distinction of animals, with respect to their manner of generation, has been into the Oviparous and Viviparous kinds; or, in other words, into those that bring an egg which is afterwards hatched into life, and those that bring forth their young alive and perfect. In one of these two ways all animals were supposed to have been produced, and all other kinds of generation were supposed to be imaginary or erroneous. But later discoveries have taught us to be more cautious in making general conclusions, and even induced many to doubt whether animal life may not be produced merely from putrefaction.

Indeed, the infinite number of creatures that putrid substances seem to give birth to, and the variety of little insects seen floating in liquors by the microscope, appear to favour this opinion. But, however this may be, the former method of classing animals can now by no means be admitted, as we find many animals that are produced neither from the womb nor from the shell, but merely from cuttings; so that to multiply life in some creatures it is sufficient only to multiply the dissection. This being the simplest method of generation, and that in which life seems to require the smallest preparation for its existence, I will begin with it, and so proceed to the two other kinds, from the meanest to the most elaborate.

The earth-worm, the millipedes, the sea-worm, and many marine insects, may be multiplied by being cut in pieces; but the polypus is noted for its amazing fertility; and from hence it will be proper to take the description. The structure of the polypus may be compared to the finger of a glove, open at one end and closed at the other. The closed end represents the tale of the polypus, with which it serves to fix itself to any substance it happens to be upon; the open end may be compared to the mouth; and, if we conceive six or eight small strings issuing from this end, we shall have a tolerable idea of its arms, which it can erect, lengthen, and contract at pleasure, like the horns of a snail. This creature is exceedingly voracious, and makes use of its arms as a fisherman does of his net, to catch and entangle such little animals as happen to come within its reach. It lengthens these arms several inches, keeps them separated from each other, and thus occupies a large space in the water in which it resides. These arms when extended are as fine as threads of silk, and have a most exquisite degree of feeling. If a small worm happens to get within the sphere of their activity, it is quickly entangled by one of these arms, and soon after the other arms come to its aid; these altogether shortening, the worm is drawn into the animal's mouth and quickly devoured, colouring the body as it is swallowed. Thus much is necessary to be observed of this animal's method of living to show that it is not of the vegetable tribe, but a real animal, performing the functions which other animals are found to perform, and endued with powers that many of them are destitute of. But what is most extraordinary remains yet to be told; for, if examined with a microscope, there are seen several little specks, like buds, which seem to pollulate from different parts of its body; and these soon after appear to be young polypi, and, like the large polypus, begin to cast their little arms about for prey in the same manner. Whatever they happen to ensnare is devoured, and gives a colour not only to their own bodies but to that of the parent—so that the same food is digested and serves for the nourishment of both. The food of the little ones passes into the large polypus, and colours its body; and this in its turn digests, and swallows its food to pass into theirs. In this manner every polypus has a new colony sprouting from its body; and these new ones, even while attached to the parent animal, become parents themselves, having a smaller colony also budding from them—all at the same time busily employed seeking for their prey, and the food of any one of them serving for the nourishment and circulating through the bodies of all the rest. This society, however, is every hour dissolving; those newly produced are seen at intervals to leave the body of the large polypus, and become shortly after the head of a beginning colony themselves.

In this manner the polypus multiplies naturally; but one may take a much readier and shorter way to increase them, and this only by cutting them in pieces. Though cut into thousands of parts, each part still retains its vivacious quality, and each shortly becomes a distinct and complete polypus; whether cut lengthwise or crosswise it is all the same—this extraordinary creature seems a gainer by our endeavours, and multiplies by

apparent destruction. The experiment had been tried times without number, and still attended with the same success. Here, therefore, naturalists who have been blamed for the cruelty of their experiments upon living animals may now boast of their increasing animal life instead of destroying it. The production of the polypus is a kind of philosophical generation. The famous Sir Thomas Brown hoped one day to be able to produce children by the same method as trees are produced; the polypus is multiplied in this manner; and every philosopher may thus, if he pleases, boast of a numerous, though I should suppose a very useless, progeny.

This method of generation from cuttings may be considered as the most simple kind, and is a strong instance of the little pains Nature takes in the formation of her lower and humbler productions. As the removal of these from inanimate to animal existence is but small, there are but few preparations made for their journey. No organs of generation seem provided—no womb to receive—no shell to protect them in their state of transition. The little repule is quickly fitted for all the offices of its humble sphere, and in a very short time arrives at the height of its contemptible perfection.

The next generation is of those animals that we see produced from the egg. In this manner all birds, most fishes, and many of the insect tribes, are brought forth. An egg may be considered as a womb detached from the body of the parent animal, in which the embryo is but just beginning to be formed. It may be regarded as a kind of incomplete delivery, in which the animal is disburthened of its young before its perfect formation. Fishes and insects, indeed, most usually commit the management of their eggs to hazard; but birds, which are more perfectly formed, are found to hatch them into maturity by the warmth of their bodies. However, any other heat of the same temperature would answer the end as well; for either the warmth of the sun or of a stove is equally efficacious in bringing the animal in the egg to perfection. In this respect, therefore, we may consider generation from the egg as inferior to that in which the animal is brought forth alive. Nature has taken care of the viviparous animal in every stage of its existence. That force which separates it from the parent separates it from life; and the embryo is shielded with unceasing protection till it arrives at exclusion. But it is different with the little animal in the egg; often totally neglected by the parent, and always separable from it, every accident may retard its growth, or even destroy its existence. Besides, art or accident may also bring this animal to a state of perfection; so that it can never be considered as a complete work of Nature in which so much is left for accident to finish or destroy.

But however inferior this kind of generation may be, the observation of it will afford great insight into that of nobler animals, as we can here watch the progress of the growing embryo in every period of its existence, and catch it in those very moments when it first seems stealing into motion. Malpighi and Haller have been particularly industrious on this subject; and, with a patience almost equalling that of the sitting hen, have attended incubation in all its stages. From them, therefore, we have an amazing history of the chicken in the egg, and of its advances into complete formation.

It would be methodically tedious to describe those parts of the egg which are well known and obvious—such as its shell, its white, and its yolk; but the disposition of these is not so apparent. Immediately under the shell lies that common membrane or skin which lines it on the inside, adhering closely to it everywhere, except at the broad end, where a little cavity is left filled with air, which increases as the animal within grows larger. Under this membrane are contained two whites, though seeming to us to be only one, each wrapped up in a membrane of its own—one white within the other. In the midst of all is the yolk, wrapped

round, likewise, in its own membrane. At each end of this are two ligaments, called "chalazæ," which are, as it were, the poles of this microcosm, being white dense substances made from the membranes, and serving to keep the white and the yolk in their places. It was the opinion of Mr. Derham that they served also for another purpose; for a line being drawn from one ligament to the other would not pass directly through the middle of the yolk, but rather towards one side, and would divide the yolk into two unequal parts, by which means these ligaments served to keep the smallest side of the yolk always uppermost; and in this part he supposed the cicatricula or first speck of life to reside—which, by being uppermost, and consequently next the hen, would be thus in the warmest situation. But this is rather fanciful than true—the incipient animal being found in all situations, and not particularly influenced by any. This cicatricula, which is the part where the animal first begins to show signs of life, is not unlike a vetch or a lentil, lying on one side of the yolk, and within its membrane. All these contribute to the little animal's convenience or support; the outer membranes and ligaments preserve the fluids in their proper places; the white serves as nourishment; and the yolk, with its membranes, after a time becomes a part of the animal's body. This is the description of a hen's egg, and answers to that of all others, how large or how small soever.

Previous to putting the eggs to the hen, our philosophers first examined the cicatricula, or little spot already mentioned, and which may be considered as the most important part of the egg. This was found in those that were impregnated by the cock to be large; but in those laid without the cock very small. It was found by the microscope to be a kind of bag, containing a transparent liquor, in the midst of which the embryo was seen to reside. The embryo resembled a composition of little threads, which the warmth of future incubation tended to enlarge, by varying and liquifying the other fluids contained within the shell, and thus pressing them either into the pores or tubes of their substance.

Upon placing the eggs in a proper warmth, either under the sun or in a stove, after six hours the vital speck begins to dilate like the pupil of the eye. The head of the chicken is distinctly seen, with the back-bone, somewhat resembling a tadpole, floating in its ambient fluid, but as yet seeming to assume none of the functions of animal life. In about six hours more the little animal is seen more distinctly; the head becomes more plainly visible, and the vertebrae of the back more easily perceivable. All these signs of preparation for life are increased in six hours more; and at the end of twenty-four hours the ribs begin to take their places, the neck begins to lengthen, and the head to turn to one side.

At this time, also, the fluids in the egg seem to have changed place; the yolk, which was before in the centre of the shell, approaches nearer to the broad end. The watery part of the white is in some measure evaporated through the shell, and the grosser part sinks to the small end. The little animal appears to turn towards the part of the broad end in which a cavity has been described, and with its yolk seems to adhere to the membrane there. At the end of forty hours the great work of life seems fairly begun, and the animal appears plainly to move; the back-bone, which is of a whitish colour, thickens; the head is turned still more on one side; the first rudiments of the eyes begin to appear; the heart beats, and the blood begins to circulate. The parts, however, as yet are fluid, but by degrees become more and more tenacious, and harden into a kind of jelly. At the end of two days, the liquor in which the chicken swims seems to increase; the head appears with two bladders in the place of eyes; the heart beats in the manner of every embryo where the blood does not circulate through the lungs. In about fourteen hours after this the chicken is grown more strong; its head, how-

ever, is still bent downwards; the veins and arteries begin to branch, in order to form the brain; and the spinal marrow is seen stretching along the back-bone. In three days the whole body of the chicken appears bent; the head, with its two eye-balls with their different humours, now distinctly appear; and five other vesicles are seen, which soon unite to form the rudiments of the brain. The outlines, also, of the thighs and wings begin to be seen, and the body begins to gather flesh. At the end of the fourth day the vesicles that form the brain approach each other; the wings and thighs appear more solid; the whole body is covered with a jelly-like flesh; the heart, that was hitherto exposed, is now covered up within the body by a very thin, transparent membrane; and, at the same time, the umbilical vessels that unite the animal to the yolk now appear to come forth from the abdomen. After the fifth and sixth days the vessels of the brain begin to be covered over; the wings and thighs lengthen; the belly is closed up and tumid; the liver is seen within it very distinctly, not yet grown red, but of a dusky white; both the ventricles of the heart are discerned, as if they were two separate hearts, beating distinctly; the whole body of the animal is covered over; and the traces of the incipient feathers are to be seen. The seventh day the head appears very large; the brain is covered entirely over; the bill begins to appear between the eyes; and the wings, the thighs, and the legs have acquired their perfect figure. Hitherto, however, the animal appears as if it had two bodies; the yolk is joined to it by the umbilical vessels that come from the belly, and is furnished with its vessels, through which the blood circulates as through the rest of the body of the chicken, making a bulk greater than that of the animal itself. But towards the end of incubation the umbilical vessels shorten the yolk, and with it the intestines are thrust up into the body of the chicken by the action of the muscles of the belly; and the two bodies are thus formed into one. During this state all the organs are found to perform their secretions; the bile is found to be separated as in grown animals; but it is a fluid, transparent, and without bitterness; and the chicken then also appears to have lungs. On the tenth the muscles of the wings appear, and the feathers begin to push out. On the eleventh, the heart, which hitherto had appeared divided, begins to unite; the arteries which belong to it join into it, like the fingers into the palm of the hand. All these appearances only come more into view because the fluids the vessels had hitherto secreted were more transparent; but as the colour of the fluids deepen their operations and circulations are more distinctly seen. As the animal thus, by the eleventh day completely formed, begins to gather strength, it becomes more uneasy in its situation, and exerts its animal powers with increasing force. For some time before it is able to break the shell in which it is imprisoned it is heard to chirrup, receiving a sufficient quantity of air for this purpose from that cavity which lies between the membrane and the shell, and which must contain air to resist the external pressure.

At length, upon the twentieth day (in some birds sooner and later in others), the enclosed animal breaks the shell within which it has been confined with its beak; and, by repeated efforts, at last procures its enlargement.

From this little history we perceive that those parts which are most conducive to life are the first that are begun: the head and the back-bone, which no doubt enclose the brain, and the spinal marrow, though both are too limpid to be discerned, are the first that are seen to exist; the beating of the heart is perceived soon after: the less noble parts seem to spring from these—the wings, the thighs, the feet, and, lastly, the bill. Whatever, therefore, the animal has double, or whatever it can live without the use of, these are latest in production—Nature first sedulously applying to the formation of the

nobler organs, without which life would be of short continuance, and begun in vain.

The resemblance between the beginning animal in the egg and the embryo in the womb is very striking; and this similitude has induced many to assert that all animals are produced from eggs in the same manner. They consider an egg excluded from the body by some, and separated into the womb by others, to be actions merely of one kind—with this only difference, that the nourishment of the one is kept within the body of the parent, and increases as the embryo happens to want the supply; the nourishment of the other is prepared all at once, and sent out with the beginning animal as entirely sufficient for its future support. But leaving this to the discussion of anatomists, let us proceed rather with facts than dissertations; and, as we have seen the progress of an oviparous animal, or one produced from the shell, let us likewise trace that of a viviparous animal, which is brought forth alive. In the investigation, Graaf has, with a degree of patience characteristic of his nation, attended the progress and increase of various animals in the womb, and minutely marked the changes they undergo. Having dissected a rabbit half an hour after impregnation, he perceived the horns of the womb that go to embrace and communicate with the ovary to be more red than before; but no other change in the rest of the parts. Having dissected another, six hours after, he perceived the follicles, or the membrane covering the eggs contained in the ovary to become reddish. In a rabbit dissected after twenty-four hours, he perceived in one of the ovaries three follicles, and in the other five, that were changed—being become from transparent dark and reddish. In one dissected after three days he perceived the horns of the womb very strictly to embrace the ovaries; and he observed three of the follicles in one of them much longer and harder than before; pursuing his inquiry, he also found two of the eggs actually separated into the horns of the womb, and each about the size of a grain of mustard-seed; these little eggs were each of them enclosed in a double membrane, the inner parts being filled with a very limpid liquor. After four days, he found in one of the ovaries four, and in the other five, follicles emptied of their eggs; and in the horns correspondent to these he found an equal number of eggs thus separated; these eggs were now grown larger than before, and somewhat of the size of duck-shot, and could be blown from the part of the womb where they were by the breath. In seven days the eggs were found of the size of a pistol-bullet, each covered with its double membrane, and these much more distinct than before. In nine days, having examined the liquor contained in one of these eggs, he found it from a limpid colour less fluid to have got a light cloud floating upon it. In ten days this cloud began to thicken, and to form an oblong body of the figure of a little worm; and in twelve days the figure of the embryo was distinctly to be perceived, and even its parts came into view. In the region of the breast he perceived two bloody specks, and two more that appeared of a whitish colour. Fourteen days after impregnation the head of the embryo was become large and transparent, the eyes prominent, the mouth open, and the rudiments of the ears beginning to appear; the back-bone, of a whitish colour, was bent towards the breast; the two bloody specks, being now considerably increased, appeared to be nothing less than the outlines of the two ventricles of the heart; and the two whitish specks on each side now appeared to be the rudiments of the lungs. Towards the region of the belly the liver began to be seen, of a reddish colour, and a little intricate mass like unravelled thread discerned, which soon appeared to be the stomach and the intestines; the legs soon after began to be seen, and to assume their natural position; and from that time forth, all the parts being formed, every day only served to develop

them still more until the thirty-first day, when the rabbit brought forth her young completely fitted for the purposes of their humble happiness.

Having thus seen the stages of generation in the meaner animals, let us take a view of its progress in MAN, and trace the feeble beginnings of our own existence. An account of the lowliness of our own origin, if it cannot amuse, will at least serve to humble us; and it may take from our pride though it fail to gratify our curiosity. We cannot here trace the variations of the beginning animal as in the former instances, for the opportunities of inspection are but few and accidental; for this reason we must be content often to fill up the blanks of our history with conjecture. And, first, we are entirely ignorant of the state of the infant in the womb immediately after conception; but we have good reason to believe that it proceeds, as in most other animals, from the egg. Anatomists inform us, that four days after conception there is found in the womb an oval substance about the size of a small pea, but longer one way than the other; this little body is formed by an extremely fine membrane enclosing a liquor a good deal resembling the white of an egg; in this may, even then, be perceived several small fibres united together, which form the first rudiments of the embryo. Besides these, another set of fibres are seen, which soon after become the placenta, or that body by which the animal is supplied with nourishment.

Seven days after conception, we can readily distinguish by the eye the first lineaments of the child in the womb. However, they are as yet without form—showing at the end of seven days pretty much such an appearance as that of the chicken after twenty-four hours, being a small jelly-like mass, yet exhibiting the rudiments of the head; the trunk is barely visible; there is likewise to be discerned a small assemblage of fibres issuing from the body of the infant, which afterwards become the blood-vessels that convey nourishment from the placenta to the child while enclosed in the womb.

Fifteen days after conception the head becomes distinctly visible, and even the most prominent features of the visage begin to appear. The nose is a little elevated; there are two black specks in the place of eyes; and two little holes where the ears are afterwards seen. The body of the embryo is also grown larger; and both above and below are seen two little protuberances, which mark the places from whence the arms and thighs are to proceed. The length of the whole body at this time is less than half an inch.

At the end of three weeks the body has received very little increase; but the legs and feet, with the hands and arms, are become apparent. The growth of the arms is more speedy than that of the legs; and the fingers are sooner separated than the toes. About this time, the internal parts are found upon dissection to become distinguishable. The places of the bones are marked by small thread-like substances, that are yet more fluid even than a jelly. Among them the ribs are perceptible, like threads also, disposed on each side of the spine; and even the fingers and toes exceed hairs in thickness.

In a month the embryo is an inch long; the body is bent forward—a situation which it almost always assumes in the womb, either because a posture of this kind is the most easy, or because it takes up the least room. The human figure is now no longer doubtful; every part of the face is distinguishable; the body is sketched out; the bowels are to be distinguished as threads; the bones are still quite soft, but in some places beginning to assume a greater rigidity; the blood-vessels that go to the placenta (which, as was said, contribute to the child's nourishment) are plainly seen issuing from the navel (being therefore called the "umbilical vessels") and going to spread themselves upon the placenta. According to Hippocrates, the male embryo develops sooner

than the female: he adds, that at the end of thirty days the parts of the body of the male are distinguishable; while those of the female are not equally so till ten days after.

In six weeks the embryo is grown two inches long; the human figure begins to grow every day more perfect—the head being still much larger in proportion to the rest of the body; and the motion of the heart is perceived almost by the eye. It has been seen to beat in an embryo of fifty days old a long time after it had been taken out of the womb.

In two months the embryo is more than two inches in length. The ossification is perceivable in the arms and thighs and in the point of the chin, the under jaw being greatly advanced before the upper. These parts, however, may as yet be considered as bony points rather than as bones. The umbilical vessels, which before went side by side, are now begun to be twisted like a rope one over the other, and go to join with the placenta, which as yet is but small.

In three months the embryo is above three inches long, and weighs about three ounces. Hippocrates observes, that not till then the mother perceives the child's motion; and he adds, that in female children the motion is not observable till the end of four months. However, this is no general rule, as there are women who assert that they perceived themselves to be quick with child, as their expression is, at the end of two months; so that this quickness seems rather to arise from the proportion between the child's strength and the mother's sensibility than from any determinate period of time. At all times, however, the child is equally alive; and consequently those juries of matrons that are to determine upon the pregnancy of criminals should not inquire whether the woman be quick, but whether she be with child; if the latter be perceivable, the former follows of course.

Four months and a half after conception the embryo is from six to seven inches long. All the parts are so augmented, that even their proportions are now distinguishable. The very nails begin to appear upon the fingers and toes; and the stomach and intestines already begin to perform their functions of receiving and digesting. In the stomach is found a liquor similar to that in which the embryo floats—in one part of the intestines a milky substance, and in the other an excrementitious one. There is also found a small quantity of bile in the gall-bladder, and some urine in its own proper receptacle. By this time, also, the posture of the embryo seems to be determined. The head is bent forward, so that the chin seems to rest upon its breast; the knees are raised up towards the head, and the legs bent backward, somewhat resembling the posture of those who sit upon their haunches. Sometimes the knees are raised so high as to touch the cheeks, and the feet are crossed over each other; the arms are laid upon the breast, while one of the hands, and often both, touch the visage; sometimes the hands are shut, and sometimes, also, the arms are found hanging down by the body. These are the most usual postures which the embryo assumes; but these it is frequently known to change; and it is owing to these alterations that the mother so frequently feels those twitches which are usually attended with pain.

The embryo thus situated is furnished by Nature with all things proper for its support; and as it increases in size its nourishment also is found to increase with it. As soon as it first begins to grow in the womb, that receptacle, from being very small, grows larger and (what is more surprising) thicker every day. The sides of a bladder, as we know, the more they are distended the more they become thin; but here, the larger the womb grows the more it appears to thicken. Within this the embryo is still farther involved, in two membranes called the "chorion" and "amnion," and

floats in a thin transparent fluid, upon which it seems in some measure to subsist. However, the great storehouse from whence its chief nourishment is supplied is called the "placenta"—a red substance somewhat resembling a sponge, that adheres to the inside of the womb, and communicates to the umbilical vessels with the embryo. These umbilical vessels, which consist of a vein and two arteries, issue from the navel of the child, and are branched out upon the placenta, where they, in fact, seem to form its substance, and, if I may so express it, seem to suck up their nourishment from the womb and the fluids contained therein. The blood thus received from the womb by the placenta, and communicated by the umbilical vein to the body of the embryo, is conveyed to the heart; where, without ever passing into the lungs as in the born infant, it takes a shorter course; for, entering the right auricle of the heart, instead of passing up into the pulmonary artery, it seems to break this partition, and goes directly through the body of the heart by an opening called the "foramen ovale," and from thence to the aorta, or great artery; by which it is driven into all parts of the body. Thus we see the placenta in some measure supplying the place of lungs; for as the little animal can receive no air by inspiration, the lungs are therefore useless. But we see the placenta converting the fluid of the womb into blood, and sending it by the umbilical vein to the heart, from whence it is despatched by a quicker and shorter circulation through the whole frame.

In this manner the embryo reposes in the womb, supplied with that nourishment which is fitted to its necessities, and furnished with those organs that are adapted to its situation. As its sensations are but few, its wants are in the same proportion; and it is probable that a sleep, with scarce any intervals, marks the earliest period of animal life. As the little creature, however, gathers strength and size, it seems to become more wakeful and uneasy; even in the womb it begins to feel the want of something it does not possess—a sensation that seems coeval with man's nature, and never leaves him till he dies. The embryo even then begins to struggle for a state more marked by pleasure and pain, and, from about the sixth month, begins to give the mother warning of the greater pain she is yet to endure. The continuation of pregnancy in woman is usually nine months; but there have been many instances when the child has lived that was born at seven; and some are found to continue pregnant a month above the usual time. When the appointed time approaches, the infant, which has for some months been giving painful proofs of its existence, now begins to increase its efforts for liberty. The head is applied downward to the aperture of the womb, and by reiterated efforts it endeavours to extend the same: these endeavours produce the pain which all women in labour feel in some degree—those of strong constitutions the least, those most weakly the most severely; since we learn that the women of Africa always deliver themselves, and are well a few hours after; while those of Europe require assistance, and recover more slowly. Thus the infant, still continuing to push with its head forward, by the repetition of its endeavours at last succeeds, and thus issues into life. The blood, which has hitherto passed through the heart, now takes a wider circuit; and the foramen ovale closes; the lungs, which had till this time been inactive, now first begin their functions; the air rushes in to distend them; and this produces the first sensation of pain, which the infant expresses by a shriek—so that the beginning of our lives as well as the end is marked with anguish.

From comparing these accounts, we perceive that the most laboured generation is the most perfect; and that the animal which, in proportion to its bulk, takes the longest time for production is always the most complete when finished. Of all others man sec: is the slowest in coming into life, as he is the slowest in coming to per-

fection; other animals of the same bulk seldom remain in the womb above six months, while he continues nine; and even after his birth appears more than any other to have his state of imbecility prolonged.

We may observe, also, that that generation is the most complete in which the fewest animals are produced. Nature, by attending to the production of one at a time, seems to exert all her efforts in bringing it to perfection; out where this attention is divided, the animals so produced come into the world with partial advantages. In this manner twins are never, at least while infants, so large or so strong as those that come singly into the world—each having in some measure robbed the other of its right, as that support which Nature meant for one has been prodigally divided.

In this manner, as those animals are the best that are produced singly, so we find that the noblest animals are ever the least fruitful. These are seen usually to bring forth but one at a time, and to place all their attention upon that alone. On the other hand, all the oviparous kinds produce an amazing plenty; and even the lower tribes of viviparous animals increase in a seeming proportion to their minuteness and imperfection. Nature seems lavish of life in the lower orders of the creation; and, as if she meant them entirely for the use of the nobler races, she appears to have bestowed greater pains in multiplying the number than in completing the kind. In this manner, while the elephant and the horse bring forth but one at a time, the spider and the beetle are seen to produce a thousand: and even among the smaller quadrupeds all the inferior kinds are extremely fertile—any one of these being found in a very few months to become the parent of a numerous progeny.

In this manner, therefore, the smallest animals multiply in the greatest proportion; and we have reason to thank Providence that the most formidable animals are the least fruitful. Had the lion and the tiger the same degree of fecundity with the rabbit or the rat, all the arts of man would be unable to oppose these fierce invaders; and we should soon perceive them become the tyrants of those who claim the lordship of the creation. But Heaven in this respect has wisely consulted the advantage of all: it has opposed to man only such enemies as he has art and strength to conquer; and as large animals require proportional supplies, Nature was unwilling to give new life where, in some measure, it denied the necessary means of subsistence.

In consequence of this pre-established order, the animals that are endowed with the most perfect methods of generation, and bring forth but one at a time, seldom begin to procreate till they have almost acquired their full growth. On the other hand, those which bring forth many engender before they have arrived at half their natural size. The horse and the bull come almost to perfection before they begin to generate; the hog and the rabbit scarce leave the teat before they become parents themselves. In whatever light, therefore, we consider this subject, we shall find that all creatures approach most to perfection whose generation most nearly resembles that of man. The reptile produced from cutting is but one degree above the vegetable; the animal produced from the egg is a step higher in the scale of existence; that class of animals which are brought forth alive are still more exalted. Of these, such as bring forth one at a time are the more complete; and amongst the foremost of these stands MAN, the great master of all, who seems to have united the perfections of all the rest in his formation.

## CHAP. III.

## THE INFANCY OF MAN.

When we take a survey of the various classes of animals, and examine their strength, their beauty, or their structure, we shall find man to possess most of those advantages united which the rest enjoy partially. Infinitely superior to all others in the powers of the understanding, he is also superior to them in the fitness and proportions of his form. He would, indeed, have been one of the most miserable beings upon earth if, with a sentient mind, he was so formed as to be incapable of obeying its impulse; but Nature has otherwise provided—as, with the most extensive intellects to command, she has furnished him with a body the best fitted for obedience.

In infancy, however, that mind and this body form the most helpless union in all Animated Nature; and if anything can give us a picture of complete imbecility, it is a man when just come into the world. The infant just born stands in need of all things without the power of procuring any. The low races of animals upon being produced are active, vigorous, and capable of self-support; but the infant is obliged to wait in helpless expectation, and its cries are its only aid to procure subsistence.

An infant just born may be said to come from one element into another; for, from the watery fluid in which it was surrounded, it now immerses into air; and its first cries seem to imply how greatly it regrets the change. How much longer it could have continued in a state of almost total insensibility in the womb is impossible to tell; but it is very probable that it could remain there some hours more. In order to throw some light upon this subject, Mr. Buffon so placed a pregnant bitch as that her puppies were brought forth in warm water, in which he kept them above half an hour at a time. However, he saw no change in the animals thus newly brought forth; they continued the whole time vigorous; and, during the whole time, it is very probable that the blood circulated through the same channels through which it passed while they continued in the womb.

Almost all animals have their eyes closed for some days after being brought into the world. The infant opens them the instant of its birth. However, it seems to keep them fixed and idle; they want that lustre which they acquire by degrees; and if they happen to move, it is rather an accidental gaze than an exertion of the act of seeing. The light alone seems to make the greatest impression upon them. The eyes of infants are sometimes found turned to the place where it is strongest; and the pupil is seen to dilate and diminish, as in grown persons, in proportion to the quantity it receives. But still the infant is incapable of distinguishing objects; the sense of seeing, like the rest of the senses, requires habit before it becomes any way serviceable. All the senses must be compared with each other, and must be made to correct the defects of one another, before they can give just information. It is probable, therefore, that if the infant could express its own sensations, it would give a very extraordinary description of the illusions which it suffers from them. The sight might, perhaps, be represented as inverting objects or multiplying them; the hearing, instead of conveying one uniform tone, might be said to bring up an interrupted succession of noises; and the touch apparently would divide one body into as many as there are fingers that grasped it. But all these errors are lost in one confused idea of existence; and it is happy for the infant that it then can make but very little use of its senses, when they could serve only to bring it false information.

If there be any distinct sensations, those of pain seem to be much more frequent and stronger than those of pleasure. The infant's cries are sufficient indications of

the uneasinesses it must at every interval endure; while, in the beginning, it has got no external marks to testify its satisfactions. It is not till after forty days that it is seen to smile; and not till that time also that the tears begin to appear, its former expressions of uneasiness being always without them. As to any other marks of the passions, the infant being as yet almost without them, it can express none of them in its visage—which, except in the act of crying and laughing, is fixed in a settled serenity. All the other parts of the body seem equally relaxed and feeble; its motions are uncertain, and its postures without choice; it is unable to stand upright; its limbs are yet bent, from the habit which it received from its position in the womb; it has not strength enough in its arms to stretch them forward, much less to grasp anything with its hands; it rests just in the posture it is laid; and, if abandoned, must continue in the same position.

Nevertheless, though this be the description of infancy among mankind in general, there are countries and races among whom infancy does not seem marked with such utter imbecility, but where the children, not long after they are born, appear possessed of a greater share of self-support. The children of Negroes have a surprising degree of this premature industry; they are able to walk at two months—or, at least, to move from one place to another, they also hang to the mother's back without any assistance, and seize the breast over the shoulder—continuing in this posture till she thinks proper to lay them down. This is very different in the children of our countries, who are seldom able to walk under a twelve-month.

The skin of children newly brought forth is always red, proceeding from its transparency, by which the blood beneath appears more conspicuous. Some say that this redness is greatest in those children that are afterwards about to have the finest complexions; and it appears reasonable that it should be so, since the thinnest skins are always the fairest. The size of a new-born infant is generally about twenty inches, and its weight about twelve pounds. The head is large, and all the members delicate, soft, and puffy. These appearances alter with its age; as it grows older, the head becomes less in proportion to the rest of the body; the flesh hardens: the bones, that before birth grew very thick in proportion, now lengthen by degrees, and the human figure more and more acquires its due dimensions. In such children, however, as are but feeble or sickly, the head always continues too big for the body—the heads of dwarfs being extremely large in proportion.

Infants, when newly born, pass most of their time in sleeping, and awake with crying—excited either by sensations of pain or of hunger. Man, when come to maturity, but rarely feels the want of food, as eating twice or thrice in the twenty-four hours is known to suffice the most voracious; but the infant may be considered as a little glutton, whose only pleasure consists in its appetite—and this, except when it sleeps, it is never easy without satisfying. Thus Nature has adapted different desires to the different periods of life—each as it seems most necessary for human support or succession. While the animal is yet forming, hunger excites it to that supply which is necessary for its growth; when it is completely formed a different appetite takes place, which incites it to communicate existence. These two desires take up the whole attention at different periods, but are very seldom found to prevail strongly together in the same age—one pleasure ever serving to repress the other; and if we find a person of full age placing a principal part of his happiness in the nature and quantity of his food, we have strong reasons to suspect that, with respect to his other appetites, he still retains a part of the imbecility of his childhood.

It is extraordinary, however, that infants, who are thus more voracious than own persons, are neverthe-

less more capable of sustaining hunger. We have several instances, in accidental cases of famine, in which the child has been known to survive the parent, and been seen clinging to the breast of its dead mother. Their little bodies, also, are more patient of cold; and we have similar instances of the mother's perishing in the snow, while the infant has been found alive beside her. However, if we examine the internal structure of infants, we shall find an obvious reason for both these advantages. Their blood-vessels are known to be much larger than in adults, and their nerves much thicker and softer; thus, being furnished with a more copious quantity of juices, both of the nervous and sanguinary kinds, the infant finds a temporary sustenance in this superfluity, and does not expire till both are exhausted. The circulation, also, being larger and quicker, supplies it with proportionable warmth, so that it is more capable of resisting the accidental rigours of the weather.

The first nourishment of infants is well known to be the mother's milk; and, what is remarkable, the infant has milk in its own breasts, which may be squeezed out by compression; this nourishment becomes less grateful as the child gathers strength, and perhaps, also, more unwholesome. However, in cold countries, which are unfavourable to propagation, and where the female has seldom above three or four children at the most during her life, she continues to suckle the child for four or five years together. In this manner the mothers of Canada and Greenland are often seen suckling two or three children of different ages at a time.

The life of infants is very precarious till the ages of three or four, from which time it becomes more secure; and when a child arrives at its seventh year it is then considered as a more certain life, as Mr. Buffon asserts, than at any other age whatever. It appears, from Simpson's Tables, that of a certain number of children born at the same time, a fourth part are found dead at the end of the first year; more than two thirds at the end of the second; and at least half at the end of the third: so that those who live to be above three years old are indulged a longer term than half the rest of their fellow-creatures. Nevertheless, life at that period may be considered as mere animal existence, and rather a preparation for than an enjoyment of those satisfactions, both of mind and body, that make life of real value; and hence it is more natural for mankind to deplore a fellow creature cut off in the bloom of life than one dying in early infancy. The one, by living up to youth, and thus wading through the disadvantageous parts of existence, seems to have earned a short continuance of its enjoyments; the infant, on the contrary, has served but a short apprenticeship to pain; and, when taken away, may be considered as rescued from a long continuance of misery.

There is something very remarkable in the growth of the human body. The embryo in the womb continues to increase still more and more till it is born. On the other hand, the child's growth is less every year till the time of puberty, when it seems to start up of a sudden. Thus, for instance, the embryo, which is an inch long in the first month, grows but one inch and a quarter in the second; it then grows one and a half in the third, two and a half in the fourth; and in this manner it keeps increasing, till in the last month of its continuance it is actually found to grow four inches, and, in the whole, about eighteen inches long. But it is otherwise with the child when born; if we suppose it eighteen inches at that time, it grows in the first year six or seven inches; in the second year it grows but four inches; in the third year about three; and so on, at the rate of about an inch and a half or two inches each year till the time of puberty, when Nature seems to make one last effort to complete her work, and unfold the whole animal machine.

The growth of the mind in children seems to correspond with that of the body. The comparative progress

of the understanding is greater in infants than in children of four years old. If we only reflect a moment on the amazing acquisitions that an infant makes in the first and second years of life, we shall have much cause for wonder. Being sent into a world where everything is new and unknown, the first months of life are spent in a kind of torpid amazement—an attention distracted by the multiplicity of objects that press to be known. The first labour, therefore, of the little learner is to correct the illusions of the senses, to distinguish one object from another, and to exert the memory so as to know them again. In this manner a child of a year old has made a thousand experiments—all which it has properly ranged and distinctly remembers. Light, heat, fire, sweets and bitters, sounds soft or terrible, are all distinguished at the end of a very few months. Besides this, every person the child knows, every individual object it becomes fond of—its rattles or its bells—may be all considered as so many new lessons to the young mind, with which it has not become acquainted without considerable exertions of the understanding. At this period of life the knowledge of every individual object cannot be acquired without the same effort which, when grown up, is employed upon the most abstract idea; everything the child sees or hears—all the marks and characters of Nature—are as much unknown, and require the same attention to attain, as if the reader were set to understand the characters of an *Æthiopic* manuscript; and yet we see in how short a time the little student begins to understand them all, and to give evident marks of early industry.

It is very amusing to pursue the young mind while employed in its first attainments. At about a year old the same necessities that first engaged its faculties increase as its acquaintance with Nature enlarges. Its studies, therefore, if I may use the expression, are no way relaxed; for having experienced what gave pleasure at one time, it desires a repetition of it from the same object; and, in order to obtain this, that object must be pointed out; here, therefore, a new necessity arises, which very often neither its little arts nor importunities can remove—so that the child is at last obliged to set about naming the objects it desires to possess or avoid. In beginning to speak, which is usually about a year old, children find a thousand difficulties. It is not without repeated trials that they come to pronounce any one of the letters, nor without an effort of the memory that they can retain them. For this reason, we frequently see them attempting a sound which they had learned, but forgot; and when they have failed, I have often seen their attempt attended with apparent confusion. The letters soonest learned are those which are most easily formed; thus A and B require an obvious disposition of the organs, and their pronunciation is consequently soon attained. Z and R, which require a more complicated position, are learned with greater difficulty. And this may, perhaps, be the reason why the children in some countries speak sooner than in others; for the letters mostly occurring in the language of one country being such as are of easy pronunciation, that language is of course more easily attained. In this manner the children of the Italians are said to speak sooner than those of the Germans—the language of the one being smooth and open, that of the other crowded with consonants, and extremely guttural.

But be this as it will, in all countries children are found able to express the greatest part of their wants by the time they arrive at two years old; and from the moment the necessity of learning new words ceases they relax their industry. It is then that the mind, like the body, seems every year to make slow advances; and, in order to spur up attention, many systems of education have been contrived.

Almost every philosopher who has written on the education of children has been willing to point out a method

of his own, chiefly professing to advance the health and improve the intellects at the same time. These are usually found to begin with finding nothing right in the common practice, and by urging a total reformation. In consequence of this nothing can be more wild or imaginary than their various systems of improvement. Some will have the children every day plunged in cold water, in order to strengthen their bodies; they will have them converse with the servants in nothing but the Latin language, in order to strengthen their minds; every hour of the day must be appointed for its own studies, and the child must learn to make these very studies an amusement; till about the age of ten or eleven it becomes a prodigy of premature improvement. Quite opposite to this, we have orders whom the courtesy of mankind also calls "philosophers:" and they will have the child learn nothing till the age of ten or eleven, at which the former has attained so much perfection; with them the mind is to be kept empty, until it has a proper distinction of some metaphysical ideas about truth; and the promising pupil is debarred the use of even his own faculties, lest they should conduct him into prejudice and error. In this manner, some men, whom fashion has celebrated for profound and fine thinkers, have given their hazarded and untried conjectures upon one of the most important subjects in the world, and the most interesting to humanity. When men speculate at liberty upon innate ideas, or the abstracted distinctions between will and power, they may be permitted to enjoy their systems at pleasure: they are harmless, although they may be wrong; but when they allege that children are to be every day plunged in cold water, and, whatever be their constitution, indiscriminately inured to cold and moisture—that they are to be kept wet in the feet to prevent their catching cold, and never to be corrected when young for fear of breaking their spirits when old; these are such noxious errors, that all reasonable men should endeavour to oppose them. Many have been the children whom these opinions, begun in speculation, have injured or destroyed in practice; and I have seen many a little philosophical martyr whom I wished, but was unable, to relieve.

If any system, therefore, be necessary, it is one that would serve to show a very plain point—that very little system is necessary. The natural and common course of education is in every respect the best—I mean that in which the child is permitted to play among its little equals, from whose similar instructions it often gains the most useful stores of knowledge. A child is not idle because it is playing about the fields or pursuing a butterfly; it is all this time storing its mind with objects upon the nature, the properties, and the relations of which future curiosity may speculate.

I have ever found it a vain task to try to make a child's learning its amusement; nor do I see what good end it would answer were it actually attained. The child, as was said, ought to have its share of play, and it will be benefited thereby; and for every reason, also, it ought to have its share of labour. The mind by early labour will be thus accustomed to fatigues and subordination; and whatever the person's future employment in life he will be better fitted to endure it: he will be thus enabled to support the drudgeries of office with content, or to fill up the vacancies of life with variety. The child, therefore, should by times be put to its duty, and be taught to know that the task is to be done or the punishment to be endured. I do not object against alluring it to duty by reward; but we well know that the mind will be more strongly stimulated by pain—and both may, upon some occasions, take their turn to operate. In this manner a child, by playing with its equals abroad and labouring with them at school, will acquire more health and knowledge than by being bred up under the wing of any speculative system-maker, and will be thus qualified for a life of activity and obedience. It

is true, indeed, that when educated in this manner the boy may not be so seemingly sensible and forward as one bred up under solitary instruction; and, perhaps, this early forwardness is more engaging than useful. It is well known that many of those children who have been such prodigies of literature before ten have not made an adequate progress to twenty. It would seem that they only began learning manly things before their time; and while others were busied in picking up that knowledge adapted to their age and curiosity, these were forced upon subjects unsuited to their years, and, upon that account alone, appearing extraordinary. The stock of knowledge in both may be equal; but with this difference—that each is yet to learn what the other knows.

But whatever may have been the acquisitions of children at ten or twelve, their greatest and most rapid progress is made when they arrive near the age of puberty. It is then that all the powers of Nature seem at work in strengthening the mind and completing the body. The youth acquires courage, and the virgin modesty; the mind with new sensations assumes new powers—it conceives with greater force, and remembers with great tenacity. About this time, therefore (which is various in different countries), more is learned in one year than in any two of the preceding; and on this age in particular the greatest weight of instruction ought to be thrown.

#### CHAP. IV.

##### OF PUBERTY.

It has been often said that the season of youth is the season of pleasures; but this can only be true in savage countries, where but little preparation is made for the perfection of human nature, and where the mind has but a very small part in the enjoyment. It is otherwise in those places where Nature is carried to the highest pitch of refinement, in which this season of the greatest sensual delight is wisely made subservient to the succeeding and more rational one of manhood. Youth with us is but a scene of preparation—a drama, upon the right conduct of which all future happiness is to depend. The youth who follows his appetites too soon seizes the cup before it has received its best ingredients, and, by anticipating his pleasures, robs the remaining parts of life of their share; so that his eagerness only produces a manhood of imbecility and an age of pain.

The time of puberty is different in various countries, and always more late in men than in women. In the warm countries of India the women are marriageable at nine or ten, and the men at twelve or thirteen. It is also different in cities (where the inhabitants lead a more soft, luxurious life) from the country, where they work harder and fare less delicately. Its symptoms are seldom alike in different persons; but it is usually known by a swelling of the breasts in one sex, and a roughness of the voice in the other. At this season, also, the women seem to acquire new beauty; while the men lose all that delicate effeminacy of countenance which they had when boys.

All countries, in proportion as they are civilised or barbarous, improve or degrade the nuptial satisfaction. In those miserable regions where strength makes the only law the stronger sex exerts its power, and becomes the tyrant over the weaker: while the inhabitant of Negroland is indolently taking his pleasure in the fields, his wife is obliged to till the grounds that serve for their mutual support. It is thus in all barbarous countries, where the men throw all the laborious duties upon the women, and, regardless of beauty, put the softer sex to those employments that must effectually destroy it.

But in countries that are half-barbarous, particularly wherever Mahometanism prevails, the men run into the very opposite extreme. Equally brutal with the former, they exert their tyranny over the weaker sex, and consider that half of the human creation as merely made to be subservient to the depraved desires of the other. The chief (and, indeed, the only) aim of an Asiatic is to be possessed of many women; and to be able to furnish a seraglio is the only tendency of his ambition. As the savage is totally regardless of beauty, he on the contrary prizes it too highly: he excludes the person who is possessed of such personal attractions from any share in the duties or employments of life; and, as if willing to engross all beauty to himself, increases the number of his captives in proportion to the progress of his fortune. In this manner he vainly expects to augment his satisfactions, by seeking from many that happiness which he ought to look for in the society of one alone. He lives a gloomy tyrant amidst wretches of his own making; he feels none of those endearments which spring from affection—none of those delicacies which arise from knowledge. His mistresses, being shut out from the world, and totally ignorant of all that passes there, have no arts to entertain his mind or calm his anxieties; the day passes with them in sullen silence or languid repose; appetite can furnish but few opportunities of varying the scene; and all that falls beyond it must be irksome expectation.

From this avarice of women (if I may be allowed to express it so) has proceeded that jealousy and suspicion which ever attends the miser: hence those low and barbarous methods of keeping the women of those countries guarded, and of making and procuring eunuchs to attend them. These unhappy creatures are of two kinds—the white and the black. The white are generally made in the country where they reside, being but partly deprived of the marks of virility; the black are generally brought from the interior parts of Africa, and are made entirely bare. These are chiefly chosen for their deformity; the thicker the lips, the flatter the nose, and the more black the teeth, the more valuable the eunuch—so that the vile jealousy of mankind here inverts the order of Nature, and the poor wretch finds himself valued in proportion to his deficiencies. In Italy—where this barbarous custom is still retained, and eunuchs are made in order to improve the voice—the laws are severely aimed against such practice; so that, being entirely prohibited, none but the poorest and most abandoned of the people still practise it upon their children. Of those served in this manner not one in ten is found to become a singer; but such is the luxurious folly of the times, that the success of one amply compensates for the failure of the rest. It is very difficult to account for the alterations which castration makes in the voice and the other parts of the body. The eunuch is shaped differently from others. His legs are of an equal thickness above and below; his knees weak—his shoulders narrow—and his beard thin and downy. In this manner his person is rendered more deformed; but his desires, as I am told, still continue the same: in Asia, some of them are actually found to have their seraglios as well as their masters. Even in our own country, we have an instance of a very fine woman being married to one of them, whose appearance was the most unpromising; and what is more extraordinary still, I am told that this couple continue perfectly happy in each other's society.

The mere necessities of life seem the only aim of the savage—the sensual pleasures are the only study of the semi-barbarian; but the refinement of sensuality by reason is the boast of real politeness. Among the merely barbarous nations, such as the natives of Madagascar or the inhabitants of Congou, nothing is desired so ardently as to prostitute their wives or daughters to strangers for the most trifling advantages: they would account it a dishonour not to be among the foremost

who are thus received into favour. On the other hand, the Mahometan keeps his wife faithful by confining her person, and would instantly put her to death if he but suspected her chastity. With the politer inhabitants of Europe both these barbarous extremes are avoided; the woman's person is left free, and no constraint is imposed but upon her affections. The passion of love—which may be considered as the nice conduct of ruder desire—is only known and practised in this part of the world; so that what other nations guard as their right the more delicate European is contented to ask as a favour. In this manner, the concurrence of mental appetite contributes to increase mutual satisfaction; and the power on one side of refusing makes every blessing more grateful when obtained by the other. In barbarous countries woman is considered merely as an useful slave; in such as are somewhat more refined she is regarded as a desirable toy; in countries entirely polished she enjoys juster privileges—the wife being considered as an useful friend and an agreeable mistress. Her mind is still more prized than her person; and without the improvement of both she can never expect to become truly agreeable—for her good sense alone can preserve what she has gained by her beauty.

Female beauty, as was said, is always seen to improve about the age of puberty; but if we should attempt to define in what this beauty consists, or what constitutes its perfection, we should find nothing more difficult to determine. Every country has its peculiar way of thinking in this respect; and even the same country thinks differently at different times. The ancients had a very different taste from what prevails at present. The eyebrows joining in the middle was considered as a peculiar grace by Tibullus, in the enumeration of the charms of his mistresses. Narrow foreheads were approved of; and scarce any of the Roman ladies that are celebrated for their other perfections but are also praised for the redness of their hair. The nose, also, of the Grecian Venus was such as would appear at present an actual deformity—as it fell in a straight line from the forehead without the smallest sinking between the eyes, without which we never see a face at present.

Among the moderns, every country seems to have a peculiar idea of beauty. The Persians admire large eye-brows, joining in the middle; the edges and corners of the eyes are tintured with black, and the size of the head is increased by a great variety of bandages formed into a turban. In some parts of India black teeth and white hair are desired with ardour; and one of the principal employments of the women of Thibet is to redden the teeth with herbs, and to make their hair white by a certain preparation. The passion for coloured teeth also obtains in China and Japan—where, to complete their idea of beauty, the object of desire must have little eyes, nearly closed, feet extremely small, and a waist far from being shapely. There are some nations of the American Indians that flatten the heads of their children, by keeping them while young squeezed between two boards, so as to make the visage much larger than it would naturally be. Others flatten the head at the top; and others still make it as round as they possibly can. The inhabitants along the western coasts of Africa have a very extraordinary taste for beauty—a flat nose, thick lips, and a jet-black complexion, are there the most indulgent gifts of Nature; such, indeed, they are all in some degree found to possess. However, they take care by art to increase these natural deformities, as they seem to us; and they have many additional methods of rendering their persons still more frightfully-pleasing. The whole body and visage is often scarred with a variety of monstrous figures, which is not done without great pain and repeated incisions—sometimes even parts of the body being cut away. But it would be endless to remark the various arts which caprice or custom has employed to distort and disfigure the body in order to render it more

pleasing; in fact, every nation, how barbarous soever, seems unsatisfied with the human figure as Nature has left it, and has its peculiar arts of heightening beauty. Painting, powdering, and cutting, boring the nose and the ears (lengthening the one and depressing the other), are arts practised in many countries—and in some degree admired in all. These arts might have been at first introduced to hide epidemic deformities; custom by degrees reconciles them to the view, till, from looking upon them with indifference, the eye at length begins to gaze with pleasure.

## CHAP. V.

### OF THE AGE OF MANHOOD.

The human body attains to its full height during the age of puberty—or at least a short time after. Some young people are found to cease growing at fourteen or fifteen; others continue their growth till two or three and twenty. During this period they are all of a slender make—their thighs and legs small, and the muscular parts as yet unfilled; but by degrees the fleshy fibres augment—the muscles swell, and assume their figure—the limbs become proportioned and rounder—and before the age of thirty the body in man has assumed the most perfect symmetry. In women the body arrives at perfection much sooner, as they arrive at the age of maturity more early; the muscles and all the other parts being weaker and less compact and solid than those of man, they require less time in coming to perfection; and as they are less in size, that size is sooner completed. Hence the persons of women are found to be as complete at twenty as those of men are found to be at thirty.

The body of a well-shaped man ought to be square; the muscles should be expressed with boldness, and the lines of the face strongly marked. In the woman, all the limbs should be rounder, the lines softer, and the features more delicate. Strength and majesty belong to the man; grace and softness are the peculiar embellishments of the other sex. In both, every part of their form declares their sovereignty over other creatures. Man supports his body erect; his attitude is that of command; and his face, which is turned towards the heavens, displays the dignity of his station. The image of his soul is painted in his visage; and the excellence of his nature penetrates through the material form in which it is enclosed. His majestic port, his sedate and resolute step, announce the nobleness of his rank. He touches the earth only with his extremity, and beholds it as if at a disdainful distance. His arms are not given him, as to other creatures, for pillars of support; nor does he lose, by rendering them callous against the ground, that delicacy of touch which furnishes him with so many of his enjoyments. His hands are made for very different purposes—to second every intention of his will, and to perfect the gifts of Nature.

When the soul is at rest, all the features of the visage seem settled in a state of profound tranquillity. Their proportion, their union, and their harmony seem to mark the sweet serenity of the mind, and give a true information of what passes within; but when the soul is excited the human visage becomes a living picture, where the passions are expressed with as much delicacy as energy—where every motion is designed by some correspondent feature—where every impression anticipates the will, and betrays those hidden agitations that he would often wish to conceal.

It is particularly in the eyes that the passions are painted, and in which we may most readily discover their beginning. The eye seems to belong to the soul more than any other organ; it seems to participate in all its motions, as well the most soft and tender as

the most tumultuous and forceful. It not only receives but transmits them by sympathy; the observing eye of one catches the secret fire from another, and the passion thus often becomes general.

Such persons as are short-sighted labour under a particular disadvantage in this respect. They are, in a manner, entirely cut off from the language of the eyes; and this gives an air of stupidity to the face which often produces very unfavourable prepossessions. However, intelligent we find such persons to be, we can scarcely be brought back from our first prejudice, and often continue in the first erroneous opinion. In this manner we are too much induced to judge of men by their physiognomy; and having, perhaps, at first caught up our judgments prematurely, they mechanically influence us all our lives after. This extends even to the very colour, or the cut of people's clothes; and we should for this reason be careful even in such trifling particulars, since they go to make up a part of the total judgment which, those we converse with may form to our advantage.

The vivacity or the languid motion of the eyes gives the strongest marks to physiognomy; and their colour contributes still more to enforce the expression. The different colours of the eye are the dark hazle, the light hazle, the green, the blue and grey, the whitish grey, and also the red. These different colours arise from the colours of the little muscles that serve to contract the pupil; and they are very often found to change colour with disorder, and with age.

The most ordinary colours are the hazle and the blue, and very often both these colours are found in the eyes of the same person. Those eyes which are called black are only of the dark hazle, which may be easily seen upon closer inspection; however, those eyes are reckoned the most beautiful where the shade is the deepest: and either in these or the blue eyes, the fire, which gives its finest expression to the eye, is more distinguishable in proportion to the darkness of the tint. For this reason, the black eyes, as they are called, have the greatest vivacity; but, probably, the blue have the most powerful effect in beauty, as they reflect a greater variety of lights, being composed of more various colours.

This variety which is found in the colour of the eyes is peculiar to man, and one or two other kinds of animals; but in general the colour in any one individual is the same in all the rest. The eyes of oxen are brown; those of sheep of a water colour; those of goats are grey; and it may also be in general remarked, that the eyes of most white animals are red; thus the rabbit, the ferret—and, even in the human race, the white Moor—all have their eyes of a red colour.

Although the eye when put into motion seems to be drawn on one side, yet it only moves round its centre; by which its coloured parts move nearer or farther from the angle of the eye-lids, or are elevated or depressed. The distance between the eyes is less in man than in any other animal; and in some of them it is so great that it is impossible that they should ever view the same object with both eyes at once, unless it be very far off. This, however, in them is rather an advantage than an inconvenience; as they are thus able to watch round them, and guard against the dangers of their precarious situation.

Next to the eyes, the features which most give a character to the face are the eye-brows—which being in some measure more apparent than the other features, are most readily distinguished at a distance. Le Brun, in giving a painter directions with regard to the passions, places the principal expression of the face in the eye-brows. From their elevation and depression, most of the furious passions are characterized; and such as have this feature extremely moveable are usually known to have an expressive face. By means of these we can imitate all the other passions, as they are raised and depressed, at command; the rest of the features are generally fixed, or,

when put into motion, they do not obey the will; the mouth and eyes in an actor, for instance, may, by being violently distorted, give a very different expression from what he would intend; but the eye-brows can scarcely be exerted improperly; their being raised denotes all those passions which pride or pleasure inspire; and their depression marks those which are the effects of contemplation and pain; and such who have this feature most at command are therefore often found to excel as actors.

The eye-lashes have an effect in giving expression to the eye, particularly when long and close; they soften its glances and improve its sweetness. Man and apes are the only animals that have eye-lashes both upon the upper and lower lids; all other animals want them on the lid below.

The eye-lids serve to guard the ball of the eye, and to furnish it with a proper moisture. The upper lid rises and falls; the lower has scarce any motion; and although their being moved depends on the will, yet it often happens that the will is unable to keep them open when sleep or fatigue oppresses the mind. In birds and amphibious quadrupeds the lower lid alone has motion; fishes and insects have no eye-lids whatever.

The forehead forms a large part of the face, and a part which chiefly contributes to its beauty. It ought to be justly proportioned—neither too round nor too flat, too narrow nor too low; and the hair should come thick and abundantly upon its extremities. It is known to everyone how much the hair tends to improve the face, and how much the being bald serves to take away from beauty. The highest part of the head is that which becomes bald the soonest, as well as that part which lies immediately above the temples. The hair under the temples and at the back of the head is seldom known to fall; and women are less apt to become bald than men. Mr. Buffon seems to think they never become bald at all; but we have too many instances of the contrary among us not to easily contradict the assertion. Of all parts or appendages of the body, the hair is that which is found to differ most in different climates; and often not only contributes to mark the country, but also the disposition, of the man. It is in general thickest where the constitution is strongest; and more glossy and beautiful where the health is most permanent. The ancients held the hair to be a sort of excrement produced like the nails—the part next the root pushing out that immediately contiguous. But the moderns have found that every hair may be truly said to live, to receive nutriment, and to fill and distend itself like the other parts of the body. The roots, they observe, do not turn grey sooner than the extremities, but the whole hair changes colour at once; and we have many instances of persons who have grown grey in one night's time. Each hair, if viewed with a microscope, is found to consist of five or six lesser ones, all wrapped up in one common covering; it appears knotted, like some sorts of grass, and sends forth branches at the joints. It is bulbous at the root, by which it imbibes its moisture from the body, and it is split at the points—so that a single hair at its end resembles a brush. Whatever be the size or the shape of the pore through which the hair issues, it accommodates itself to the same—being either quick as they are large, small as they are less, or round, triangular, and variously formed as the pores happen to be various. The hair takes its colour from the juices flowing through it; and it is found that this colour differs in different tribes and races of people. The Americans and the Asiatics have their hair black, thick, straight, and shining; the inhabitants of the torrid climates of Africa have it black, short, and woolly; the people of Scandinavia have it red, long, and curled; and those of our own and the neighbouring countries are found with hair of various colours. However, it is supposed by many that every man resembles in his disposition the

inhabitants of those countries whom he resembles in the colour and the nature of his hair; so that the black are said, like the Asiatics, to be grave and acute—the red, like the Gothic nations, to be choleric and bold. However this may be, the length and strength of the hair is a general mark of a good constitution; and as that hair which is strongest is most commonly curled, so curled hair is generally accounted among us a token of beauty. The Greeks, however, had a very different idea of beauty in this respect, and seem to have taken one of their peculiar national distinctions from the length and straightness of the hair.

The nose is the most prominent feature in the face; but as it has scarce any motion, and that only in the strongest passions, it rather adds to the beauty than to the expression of the countenance. However, I am told by the skilful in this branch of knowledge that wide nostrils add a great deal to the bold and resolute air of the countenance; and where they are narrow, though it may constitute beauty, it seldom improves expression. The form of the nose and its advanced position are peculiar to the human visage alone. Other animals for the most part have nostrils with a partition between them; but none have an elevated nose. Apes themselves have scarce anything else of this feature but the nostrils—the rest of the feature lying flat upon the visage, and scarce higher than the cheek-bones. Among all the tribes of savage men, also, the nose is very flat; and I have seen a Tartar who had scarce anything else but two holes through which to breathe.

The mouth and lips, next to the eyes, are found to have the greatest expression. The passions have great power over this part of the face; and the mouth marks its different degrees by its different forms. The organ of speech still more animates this part, and gives it more life than any other feature in the countenance. The ruby colour of the lips, and the white enamel of the teeth, give it such a superiority over every other feature that it seems to make the principal object of our regard. In fact, the whole attention is fixed upon the lips of the speaker; however rapid his discourse—however various the subject, the mouth takes correspondent situations; and deaf men have been often found to see the force of those reasonings which they could not hear, understanding every word as it was spoken.

The under jaw in man possesses a greater variety of motions; while the upper has been thought by many to be quite immovable. However, that it moves in man, a very easy experiment will suffice to convince us. If we keep the head fixed with anything between our teeth, the edge of a table for instance, and then open our mouths, we shall find that both jaws recede from it at the same time; the upper jaw rises and the lower falls, and the table remains untouched between them. The upper jaw has motion as well as the under; and, what is remarkable, it has its proper muscles behind the head for thus raising and depressing it. Whenever, therefore, we eat, both jaws move at the same time, though very unequally; for the whole head moving with the upper jaw, of which it makes a part, its motions are thus less observable. In the human embryo the under jaw is very much advanced before the upper. In the adult it hangs a good deal more backward; and those whose upper and under row of teeth are equally prominent, and strike directly against each other, are what the painters call under-bung; and they consider this as a great defect in beauty. The under jaw in a Chinese face falls much more backward than with us; I am told the difference is half an inch when the mouth is shut naturally. In instances of the most violent passion the under jaw has often an involuntary quivering motion; often, also, a state of languor produces another, which is that of yawning. Everyone knows how very sympathetic this kind of languid motion is; and that for one person to yawn is sufficient to set all the rest of the

company a yawning. A ridiculous instance of this was commonly practised upon the famous M'Laurin, one of the professors at Edinburgh. He was very subject to have his jaw dislocated; so that when he opened his mouth wider than ordinary, or when he yawned, he could not shut it again. In the midst of his harangues, therefore, if any of his pupils began to be tired of his lecture, he had only to gape or yawn, and the professor instantly caught the sympathetic affection; so that he thus continued to stand speechless, with his mouth wide open, till his servant from the next room was called in to set his jaw again.

When the mind reflects with regret upon some good unattained, or lost it feels an internal emotion, which, acting upon the diaphragm, and that upon the lungs, produces a sigh; this, when the mind is strongly affected, is repeated; sorrow succeeds these first emotions; and tears are often seen to follow: sobbing is the sigh still more invigorated; and lamentation or crying proceeds from the continuance of the plaintive tone of the voice, which seems to implore pity. There is yet a silent agony in which the mind appears to disdain all external help, and broods over its distresses with gloomy reserve. This is the most dangerous state of mind; accidents or friendship may lessen the louder kinds of grief; but all remedies for this must be had from within: and there, despair, too, often finds the most deadly enemy.

Laughter is a sound of the voice interrupted and pursued for some continuance. The muscles of the belly and the diaphragm are employed in its slightest exertions, but those of the ribs are strongly agitated in the louder; and the head sometimes is thrown backward in order to raise them with greater ease. The smile is often an indication of kindness and good will; it is also often used as a mark of contempt and ridicule.

Blushing proceeds from different passions, being produced by shame, anger, pride, and joy. Paleness is often also the effect of anger, and almost ever attendant on fright and fear. These alterations in the colour of the countenance are entirely involuntary; all the other expressions of the passions are in some small degree under control; but blushing and paleness betray our secret purposes; and we might as well attempt to stop them as the circulation of the blood by which they are caused.

The whole head, as well as the features of the face, takes peculiar attitudes from its passions: it bends forward to express humility, shame, or sorrow; it is turned to one side in languor or in pity; it is thrown with the chin forward in arrogance and pride; erect in self-conceit and obstinacy; it is thrown backwards in astonishment; and combines its motions to the one side and the other to express contempt, ridicule, anger, and resentment. Painters, whose study leads to the contemplation of external forms, are much more adequate judges of these than any naturalist can be; and it is with these a general remark, that no one passion is regularly expressed on different countenances in the same manner; that grief often sits upon the face like joy; and pride assumes the air of passion. It would be vain, therefore, in words to express their general effect, since they are often as various as the countenances they sit upon; and in making this distinction nicely lies all the skill of the physiognomist. It being able to distinguish what parts of the face is marked by Nature, and what by the mind—what part has been originally formed and what made by habit, constitutes this science; upon which the ancients so much valued themselves, and which we at present so little regard. Some, however, of the most acute men among us have paid great attention to this art; and by long practice have been able to give some character of every person whose face they examined. Montaigne is well known to have disliked those men who shut one eye in looking upon any object; and Fielding asserts, that he never knew a person with a steady glowering smile but he found him a rogue. However, most of these

observations, tending to a discovery of the mind by the face, are merely capricious, and Nature has kindly hidden our hearts from each other to keep us in good humour with our fellow-creatures.

The parts of the head which give the least expression to the face are the ears; and they are generally found hidden under the hair. These, which are immoveable, and make so small an appearance in man, are very distinguishing features in quadrupeds. They serve in them as the principal marks of the passion; the ears discover their joys or their terrors with tolerable precision, and denote all their internal agitations. The smallest ears in men are said to be the most beautiful; but the largest are found to be the best for hearing. There are some savage nations who bore their ears, and so draw that part down, that the tips of the ears are seen to rest upon their shoulders.

The strange variety in the different customs of men appears still more extravagant in their manner of wearing their beards. Some, and among others the Turks, cut the hair off their heads and let their beards grow. The Europeans, on the contrary, shave their beards and wear their hair. The Negroes shave their heads in figures at one time, in stars at another, in the manner of friars; and still more commonly in alternate stripes; and their little boys are shaved in the same manner. The Talapoins of Siam shave the heads and eye-brows of such children as are committed to their care. Every nation seems to have entertained different prejudices at different times in favour of one part or another of the beard. Some have admired the hair upon the cheeks on each side, as we see with some low-bred men among ourselves who want to be fine. Some like the hair lower down; some choose it curled; and others like it straight. Some have cut it into a peak; and others shave all but the whisker. This particular part of the beard was highly prized among the Spaniards; till of late a man without whiskers was considered as unfit for company; and where Nature had denied them, Art took care to supply the deficiency. We are told of a Spanish general who, when he borrowed a large sum of money from the Venetians, pawned his whisker, which he afterwards took proper care to release. Kingson assures us that a considerable part of the religion of the Tartars consists in the management of their whiskers; that they waged a long and bloody war with the Persians, declaring them infidels, merely because they would not give their whiskers the orthodox cut. The kings of Persia carried the care of their beards to a ridiculous excess when they chose to wear them matted with gold-thread; and even the kings of France of the first races had them knotted and buttoned with gold. But of all nations, the Americans take the greatest pains in cutting their hair and plucking their beards. The under part of the beard and all but the whisker they take care to pluck up by the roots; so that many have supposed them to have no hair naturally growing on that part; and even Linnaeus has fallen into that mistake. Their hair is also cut into bands, and no small care employed in adjusting the whisker. In fact, we have a very wrong idea of savage finery, and are apt to suppose that, like the beasts of the forest, they rise and are dressed with a shake; but the reverse is true—for no birth-night beauty takes more time or pains in adorning her person than they. When the Cherokee kings were over here, I remember having to wait three hours during the time they were dressing. They never would venture to make their appearance till they had gone through the tedious ceremonies of the toilet; they had their boxes of oil or ochre, their fat and their perfumes, like the most effeminate beau, and generally took up four hours in dressing before they considered themselves as fit to be seen. We must not, therefore, consider a delicacy in point of dress as a mark of refinement, since savages are much more difficult in this particular than the most fashionable or tawdry European.

The more barbarous the people the fonder of finery. In Europe, the lustre of jewels and the splendour of the most brilliant colours are generally given up to women, or to the weakest part of the other sex who are willing to be contemptibly fine; but in Asia these trifling fineries are eagerly sought after by every condition of men; and, as the proverb has it, we find the richest jewels in an *Aethiop's* ear. The passion for glittering ornaments is still stronger among the absolute barbarians, who often exchange their whole stock of provisions, and whatever else they happen to be possessed of, with our seamen for a glass bead or a looking-glass.

Although fashions have arisen in different countries from fancy and caprice, these when they become general deserve examination. Mankind have always considered it is a matter of moment; and they will ever continue desirous of drawing the attention of each other by such ornaments as mark the riches, the power, or the courage of the wearer. The value of these shining stones, which have at all times been considered as precious ornaments, is entirely founded upon their scarceness or their brilliancy. It is the same, likewise, with respect to those shining metals the weight of which is so little regarded when spread over our clothes. These ornaments are rather designed to draw the attention of others than to add to any enjoyments of our own; and few there are that these ornaments will not serve to dazzle, and who can coolly distinguish between the metal and the man.

All things rare and brilliant will therefore ever continue to be fashionable while men derive greater advantage from opulence than virtue—while the means of appearing considerable are more easily acquired than the title to be considered. The first impression we generally make arises from our dress; and this varies in conformity to our inclinations and the manner in which we desire to be considered. The modest man, or he who would wish to be thought so, desires to show the simplicity of his mind by the plainness of his dress; the vain man, on the contrary, takes a pleasure in displaying his superiority, and is willing to incur the spectator's dislike so he but excite his attention.

Another point of view which men have in dressing is to increase the size of their figure, and to take up more room in the world than Nature seems to have allotted them. We desire to swell out our clothes by the stiffness of art, and raise our heels while we add to the largeness of our heads. How bulky soever our dress may be, our vanities are still more bulky. The largeness of the doctor's wig arises from the same pride with the smallness of the beau's queue: both want to have the size of their understanding measured by the size of their heads.

There are some modes that seem to have a more reasonable origin, which is to hide or lessen the defects of Nature. To take men altogether, there are many more deformed and plain than beautiful and shapely. The former, as being the most numerous, give law to fashion; and their laws are generally such as are made in their own favour. The women begin to colour their cheeks with red when the natural roses are faded; and the younger are obliged to submit, though not compelled by the same necessity. In all parts of the world this custom prevails more or less; and powdering and frizzing the hair, though not so general, seem to have arisen from a similar control.

But leaving the draperies of the human picture, let us return to the figure unadorned by Art. Man's head, whether considered externally or internally, is differently formed from that of all other animals—the monkey-kind only excepted, in which there is a striking similitude. There are some differences, however, which we shall take notice of in another place. The bodies of all quadruped animals are covered with hair; but the head of man seems the part most adorned, and that more abundantly than in any other animal.

There is a very great variety in the teeth of animals: some have them above and below; others have them in the under jaw only: in some they stand separate from each other; while in some they are continued and united. The palate of some fishes is nothing else but a bony plate studded with points, which perform the offices of teeth. All these substances in every animal derive their origin from the nerves; the substance of the nerves hardens by being exposed to the air; and the nerves that terminate in the mouth being thus exposed acquire a bony solidity. In this manner the teeth and nails are formed in man; and in this manner, also, the beak, the hoofs, the horns, and the talons of other animals are found to be produced.

The neck supports the head and unites it to the body. This part is much more considerable in the generality of quadrupeds than in man. But fishes and other animals that want lungs similar to ours have no neck whatsoever. Birds in general have the neck longer than any other kind of animals: those of them which have short claws have also short necks; those, on the contrary, that have them long are found to have the neck in proportion. In men, there is a lump upon the wind-pipe, formed by the thyroid cartilage, which is not to be seen in women; an Arabian fable says that this is a part of the original apple, which has stuck in the man's throat by the way, but that the woman swallowed her part of it down.

The human breast is outwardly formed in a very different manner from that of other animals. It is larger in proportion to the size of the body; and none but man, and such animals as make use of their fore-feet as hands—such as monkeys, bats, and squirrels—are found to have those bones called the "claviculae," or, as we usually term them, the "collar-bones." The breasts in women are larger than in men; however, they seem formed in the same manner; and sometimes milk is found in the breasts of man as well as in those of women. Among animals there is a great variety in this part of the body. The teats of some, as in the ape and the elephant, are like those of men, being but two, and placed on each side of the breast. The teats of the bear amount to four. The sheep has but two, placed between the hinder legs. Other animals, such as the bitch and the sow, have them all along the belly; and, as they produce many young, they have a great many teats for their support. The form, also, of the teats varies in different animals; and in the same animal at different ages. The bosom in females seems to unite all our ideas of beauty, where the outline is continually changing, and the gradations are soft and regular.

The graceful fall of the shoulders, both in man and woman, constitute no small part of beauty. In apes, though otherwise made like us, the shoulders are high, and drawn up on each side towards the ears. In man they fall by a gentle declivity; and the more so in proportion to the beauty of his form. In fact, being high-shouldered is not without reason considered as a deformity, for we find very sickly persons are always so; and people when dying are ever seen with their shoulders drawn up in a surprising manner. The muscles that serve to raise the ribs mostly rise near the shoulders; and the higher we raise the shoulders we the more easily raise the ribs likewise. It happens, therefore, in the sickly and the dying, who do not breathe without labour, that to raise the ribs they are obliged to call in the assistance of the shoulders; and thus their bodies assume from habit that from which, they are so frequently obliged to assume. Women with child, also, are usually seen to be high-shouldered; for the weight of the inferior parts drawing down the ribs, they are obliged to use every effort to elevate them, and thus they raise the shoulders of course. During pregnancy, also, the shape, not only of the shoulders but also of the breast, and even the features of the face, are greatly altered; for the whole upper fore-part of the body is covered with a broad thin skin, called the *myoides*;

which being at that time drawn down, it also draws down with it the skin, and, consequently, the features of the face. By these means the visage takes a particular form; the lower eye-lids and the corners of the mouth are drawn downwards; so that the eyes are enlarged and the mouth lengthened; and women in these circumstances are said by the midwives to be "all mouth and eyes."

The arms of men but very little resemble the fore-feet of quadrupeds, and much less the wings of birds. The ape is the only animal that is possessed of hands and arms; but these are much more rudely fashioned, and with less exact proportion, than in men—the thumb not being so well opposed to the rest of the fingers in their hands as in ours.

The form of the back is not much different in man from that of other quadruped animals, only that the reins are muscular in him, and stronger. The buttock, however, in man is different from that of all other animals whatsoever. What goes by that name in other creatures is only the upper part of the thigh; man being the only animal that supports himself perfectly erect, the largeness of this part is owing to this peculiarity of his position.

Man's feet, also, are different from those of all other animals, those even of apes not excepted. The foot of the ape is rather a kind of awkward hand; its toes, or rather fingers, are long, and that of the middle longest of all. This foot also wants the heel, as in man; the sole is narrower, and less adapted to maintain the equilibrium of the body in walking, dancing, or running.

The nails are less in man than in any other animals: if they were much longer than the extremities of the fingers they would rather be prejudicial than serviceable, and obstruct the management of the hand. Such savages as let them grow long make use of them in fleecing animals, in tearing their flesh, and such like purposes; however, though their nails are considerably larger than ours, they are by no means to be compared to the hoofs or the claws of other animals. They may sometimes be seen longer, indeed, than the claws of any animal whatsoever; as we learn that the nails of some of the learned men in China are longer than their fingers. But these want that solidity which might give force to their exertions; and could never, in a state of nature, have served them for annoyance or defence.

There is little known exactly with regard to the proportion of the human figure; and the beauty of the best statues is better conceived by observing than by measuring them. The statues of antiquity, which were at first copied after the human form, are now become the models of it; nor is there one man found whose person approaches to those inimitable performances that have thus in one figure united the perfections of many. It is sufficient to say, that, from being at first models, they are now become originals; and are used to correct the deviations in that form from whence they were taken. I will not, however, pretend to give the proportions of the human body as taken from these, there being nothing more arbitrary, and which good painters themselves so much condemn. Some, for instance, who have studied after these, divide the body into ten times the length of the face, and others into eight. Some pretend to tell us that there is a similitude of proportion in different parts of the body. Thus, that the hand is the length of the face; the thumb the length of the nose; the space between the eyes is the breadth of an eye; that the breadth of the thigh at the thickest part is double that of the thickest part of the leg, and treble the smallest; that the arms extended are as long as the figure is high; that the legs and thighs are half the length of the figure. All this, however, is extremely arbitrary; and the excellence of a shape or the beauty of a statue results from the attitude and position of the whole, rather than any established measurements, begun without experience

and adopted by caprice. In general it may be remarked that the proportions alter in every age, and are obviously different in the two sexes. In woman the shoulders are narrower, and the neck proportionably longer than in men. These proportions, however, vary greatly at different ages. In infancy the upper parts of the body are much larger than the lower; the legs and thighs do not constitute anything like half the height of the whole figure; in proportion as the child increases in age the inferior parts are found to lengthen—so that the body is not equally divided until it has acquired its full growth.

The size of men varies considerably. Men are said to be tall who are from five feet eight inches to six feet high. The middle stature is from five feet five to five feet eight; and those are said to be of small stature who fall under these measures. However, it ought to be remarked that the same person is always taller in the morning than upon going to bed at night; sometimes there is more than an inch difference. Few persons are sensible of this remarkable variation; and I am told it was first perceived in England by a recruiting-officer. He often found that those men whom he had enlisted for soldiers, and answered to the appointed standard at one time, fell short of it when they came to be measured before the colonel at head-quarters. This diminution in their size proceeded from the different times of the day and the different states of the body when they happened to be measured. If, as was said, they were measured in the morning after the night's refreshment, they were found to be commonly half an inch, and very often a whole inch, taller than if measured after the fatigues of the day; if they were measured when fresh in the country, and before a long fatiguing march to the regiment, they were found to be an inch taller than when they arrived at their journey's end. All this is now well known among those who recruit for the army; and the reason of this difference of stature is obvious. Between all the joints of the back-bone, which is composed of several pieces, there is a glutinous liquor deposited, which serves, like oil in a machine, to give the parts an easy play upon each other. This lubricating liquor, or synovia, as the anatomists call it, is poured in during the season of repose, and is consumed by exercise and employment; so that in a body after hard labour there is scarce any of it remaining—all the joints growing stiff, and their motion becomes hard and painful. It is from hence, therefore, that the body diminishes in stature; for this moisture being drained away from between the numerous joints of the back-bone, they lie closer upon each other, and their whole length is thus sensibly diminished; but sleep, by restoring the fluid, again swells the spaces between the joints, and the whole is extended to its former dimensions.

As the human body is thus often found to differ from itself in size, so it is found to differ in its weight also; and the same person, without any apparent cause, is found to be heavier at one time than another. If, after having eaten a hearty dinner, or having drank hard, the person should find himself thus heavier, it would appear no way extraordinary; but the fact is, the body is very often found heavier some hours after eating a hearty meal than immediately succeeding it. If, for instance, a person fatigued by a hard day's labour should eat a plentiful supper, and then get himself weighed upon going to bed, after sleeping soundly, if he is again weighed, he will find himself considerably heavier than before; and this difference is often found to amount to a pound, or sometimes to a pound and a half. From whence this adventitious weight is derived is not easy to conceive; the body during the whole night appears rather plentifully perspiring than imbibing any fluid—rather losing than gaining moisture; however, we have no reason to doubt but that, either by the lungs or, perhaps, by a peculiar set of pores, it is all this time inhal-

ing a quantity of fluid, which thus increases the weight of the whole body upon being weighed the following morning.

Although the human body is externally more delicate than any of the quadruped kind, it is, notwithstanding, extremely muscular, and, perhaps, for its size stronger than that of any other animal. If we should offer to compare the strength of the lion with that of man, we should consider that the claws of this animal give us a false idea of its power; we ascribe to its force what is only the effects of its arms. Those which man has received from Nature are not offensive; happy had Art never furnished him with any more terrible than those which arm the paws of the lion.

But there is another manner of comparing the strength of man with that of other animals; namely, by the weights which either can carry. We are assured that the porters of Constantinople carry burdens of nine hundred pounds weight. Mr. Desaguliers tells us of a man, who, by distributing weights in such a manner as that every part of his body bore its share, he was thus able to raise a weight of two thousand pounds. A horse, which is about seven times our bulk, would be thus able to raise a weight of fourteen thousand pounds, if its strength were in the same proportion to its size. But the truth is, a horse will not carry upon its back more than a weight of two or three hundred pounds; while a man of confessedly inferior strength is thus able to support two thousand. Whence comes this seeming superiority? The answer is obvious. Because the load upon a man's shoulders is placed to the greatest advantage; while, upon the horse's back, it is placed at the greatest disadvantage. Let us suppose, for a moment, the man standing as upright as possible under the great load above mentioned. It is obvious that all the bones of his body may be compared to a pillar supporting a building, and that his muscles have scarce any share in this dangerous duty. However, they are not entirely inactive; as man, let him stand never so upright, will have some bending in the different parts of his body. The muscles, therefore, give the bones some assistance, and that with the greatest possible advantage. In this manner, a man has been found to support two thousand pounds weight; but may be capable of supporting a still greater. The manner in which this is done is by strapping the load round the shoulders of the person who is to bear it by a machine something like that by which milk-vessels or water-buckets are carried. The load being thus placed on a scaffold on each side, contrived for that purpose, and the man standing erect in the midst, all parts of the scaffold except where the man stands are made to sink; and thus the man maintaining his position, the load, whatever it is, becomes suspended, and the column of his bones may be fairly said to support it. If, however, he should but ever so little give way, he must inevitably drop; and no power of his can raise the weights again. But the case is very different with regard to a load laid upon a horse. The column of the bones there lies a different way; and a weight of five hundred pounds, as I am told, would break the back of the strongest horse that could be found. The great force of a horse and other quadrupeds is exerted when the load is in such a position as that the column of the bones can be properly applied, which is lengthwise. When, therefore, we are to estimate the comparative strength of a horse, we are not to try what he can carry but what he can draw; and, in this case, his amazing superiority over man is easily discerned; for one horse can draw a load that ten men cannot move. And in some cases it happens that a draught-horse draws the better for being somewhat loaded; for, as the peasants say, the load upon the back keeps him the better to the ground.

There is still another way of estimating human strength by the perseverance and agility of our motions. Men

who are exercised in running outstrip horses—or, at least, hold their speed for a longer continuance. In a journey, also, a man will walk down a horse; and, after they have both continued to proceed for several days, the horse will be quite tired, and the man will be fresher than in the beginning. The king's messengers of Ispahan, who are runners by profession, go thirty-six leagues in fourteen hours. Travellers assure us that the Hottentots outstrip lions in the chase; and that the savages who hunt the elk pursue with such speed, that they at last tire down and take it. We are told many very surprising things of the great swiftness of the savages, and of the long journeys they undertake on foot through the most craggy mountains, where there are no paths to direct nor houses to entertain them. They are said to perform a journey of twelve hundred leagues in less than six weeks. But notwithstanding what travellers report of this matter, I have been assured from many of our officers and soldiers, who compared their own swiftness with that of the native Americans during the last war, that although the savages held out, and, as the phrase is, had better bottoms, yet, for a spurt, the Englishmen were more nimble and speedy.

Nevertheless, in general civilized man is ignorant of his own powers; he is ignorant how much he loses by effeminacy, and what might be acquired by habit and exercise. Here and there, indeed, men are found among us of extraordinary strength; but that strength, for want of opportunity, is seldom called into exertion. Among the ancients it was a quality of much greater use than at present; as in war the same man that had strength sufficient to carry the heaviest armour had strength sufficient also to strike the most fatal blow. In this case his strength was at once his protection and his power. We ought not to be surprised, therefore, when we hear of one man terrible to an army and irresistible in his career, as we find some generals represented in ancient history. But we may be very certain that this prowess was exaggerated by flattery and exalted by terror. An age of ignorance is ever an age of wonder. At such times, mankind, having no just ideas of the human powers, are willing rather to represent what they wish than what they know, and exalt human strength to fill up the whole sphere of their limited conceptions. Great strength is an accidental thing; two or three in a country may possess it, and may have a claim to heroism. But what may lead us to doubt of the veracity of these accounts is, that the heroes of antiquity are represented as the sons of heroes; their amazing strength is delivered down from father to son; and this we know to be contrary to the course of Nature. Strength is not hereditary, although titles are; and I am induced to believe that this great tribe of heroes, who were all represented as the descendants of heroes, are more obligated to their titles than to their strength for their characters. With regard to the shining characters in Homer, they are all represented as princes and as the sons of princes; while we are told of scarce any share of prowess in the meaner men of the army, who are only brought into the field for these to protect or to slaughter. But nothing can be more unlikely than that those men, who were bred in the luxury of courts, should be strong; while the whole body of the people, who received a plainer and more simple education, should be comparatively weak. Nothing can be more contrary to the general laws of Nature than that all the sons of heroes should thus inherit not only the kingdoms, but the strength, of their forefathers; and we may conclude that they owe the greatest share of their imputed strength rather to the dignity of their stations than the force of their arms; and, like all fortunate princes, their flatterers happened to be believed. In later ages, indeed, we have some accounts of amazing strength which we can have no reason to doubt of; but in these, Nature is found to pursue her ordinary course—and we find their strength

accidental. We find these strong men among the lowest of the people, and gradually rising into notice as this superiority had opportunity of being seen. Of this number was the Roman tribune, who went by the name of the second Achilles, who, with his own hand, is said to have killed at different times three hundred of the enemy; and when treacherously set upon by twenty-five of his own countrymen, although then past his sixtieth year, he killed fourteen of them before he was slain. Of this number was Milo, who when he stood upright could not be forced out of his place. Pliny also tells us of one Athanatus, who walked across the stage at Rome loaded with a breast-plate weighing five hundred pounds, and buskins of the same weight. But of all the prodigies of strength of whom we have any accounts in Roman history, Maximin, the emperor, is decidedly the foremost. Whatever we are told relative to him is well attested; his character was too exalted not to be thoroughly known; and that very strength for which he was celebrated at last procured him no less a reward than the empire of the whole world. Maximin was above nine feet in height, and the best proportioned man in the whole empire. He was a Thracian by birth; and, from being a simple herdsman, rose through the gradations of office until he came to be Emperor of Rome. The first opportunity he had of exerting his strength was in the presence of all the citizens, in the theatre, where he overthrew twelve of the strongest men in wrestling, and outstript two of the fleetest horses in running, all in one day. He could draw a chariot so heavily laden that two strong horses could not move; he could break a horse's jaw with his fist, and its thigh with a kick. In war he was always foremost and invincible; happy had it been for him and his subjects if, from being formidable to his enemies, he had not become still more so to his subjects; he reigned for some time with all the world his enemy—all mankind wishing him dead, yet none daring to strike the blow. As if fortune had resolved that through life he should continue unconquerable, he was killed at last by his own soldiers while he was sleeping. We have many other instances in later ages of very great strength, and not fewer of amazing swiftness; but these merely corporeal perfections are now considered as of small advantage, either in war or in peace. The invention of gunpowder has in some measure levelled all force to one standard, and has wrought a total change in martial education through all parts of the world. In peace, also, the invention of new machines every day, and the application of the strength of the lower animals to the purposes of life, have rendered human strength less valuable. The boast of corporeal force is therefore confined to savage nations—where, those arts not being introduced, it may still be needful; but in more civilised countries few will boast of that strength which other animals can be taught to exert to as useful purposes as they.

If we compare the largeness and thickness of our muscles with those of any other animal, we shall find that in this respect we have the advantage; and if strength or swiftness depended upon the quantity of muscular flesh alone, I believe that in this respect we should be more active and powerful than any other. But this is not the case; a great deal more than the size of the muscles goes to constitute activity or force; and it is not he who has the thickest legs that can make the best use of them. Those, therefore, who have written elaborate treatises on muscular force, and have estimated the strength of animals by the thickness of their muscles, have been employed to very little purpose. It is in general observed that thin and raw-boned men are always stronger and more powerful than such as are seemingly more muscular—as in the former all the parts have better room for their exertions.

Women want much of the strength of men; and in some countries the stronger sex have availed themselves

of this superiority in cruelly and tyrannically enslaving those who were made with equal pretensions to a share in all the advantages life can bestow. Savage nations confine their women to a life of continual labour: upon them rest all the drudgeries of domestic duty; while the husband, indolently reclined in his hammock, is served from the fruits of her industry. From this negligent situation he is seldom roused except by the calls of appetite—when it is necessary, either by fishing or hunting, to make a variety in his entertainments. A savage has no idea of taking pleasure in exercise; he is surprised to see a European walk forward for his amusement, and then return back again. As for his part, he could be contented to remain for ever in the same situation, perfectly satisfied with sensual pleasures and undisturbed repose. The women of these countries are the greatest slaves upon earth; sensible of their weakness, and unable to resist, they are obliged to suffer those hardships which are naturally inflicted by such as have been taught that nothing but corporeal force ought to give pre-eminence. It is not, therefore, till after some degree of refinement that women are treated leniently, and not till the highest degree of politeness that they are permitted to share in all the privileges of man. The first impulse of savage nature is to confirm their slavery—the next of half-barbarous nations is to appropriate their beauty, and that of the perfectly polite to engage their affections. In civilised countries, therefore, women have united the force of modesty to the power of their natural charms; and thus they have obtained that superiority over the mind which they are unable to extort by their strength.

## CHAP. VI.

### OF SLEEP AND HUNGER.

As man, in all the privileges he enjoys and the powers he is invested with, has a superiority over all other animals, so in his necessities he seems inferior to the meanest of them all. Nature has brought him into life with a greater variety of wants and infirmities than the rest of her creatures—unarmed in the midst of enemies. The lion has natural arms—the bear natural clothing, but man is destitute of all such advantages; and from the superiority of his mind alone he is to supply the deficiency. The number of his wants, however, were merely given in order to multiply the number of his enjoyments; since the possibility of being deprived of any good teaches him the value of its possession. Were man born with those advantages which he learns to possess by industry, he would very probably enjoy them with a blunter relish: it is by being naked that he knows the value of a covering; it is by being exposed to the weather that he learns the comforts of a habitation. Every want thus becomes a means of pleasure in the redressing; and the animal that has most desires may be said to be capable of the greatest variety of happiness.

Beside the thousand imaginary wants peculiar to man, there are two which he has in common with all other animals, and which he feels in a more necessary manner than they. These are the wants of sleep and hunger. Every animal that we are acquainted with seems to endure the want of these with much less injury to health than man; and some are most surprisingly patient in sustaining both. The little domestic animals that we keep about us may often set a lesson of calm resignation in supporting want and watchfulness to the boasted philosopher. They receive their pittance at uncertain intervals, and wait its coming with cheerful expectation. We have instances of the dog and the cat living in this manner, without food, for several days, and yet still preserving their attachment to the tyrant that oppresses

them—still ready to exert their little services for his amusement or defence. But the patience of these is nothing to what the animals of the forest endure. As these mostly live upon accidental carnage, so they are often known to remain without food for several weeks together. Nature, kindly solicitous for their support, has also contracted their stomachs to suit them for their precarious way of living, and kindly, while it abridges the banquet, lessens the necessity of providing for it. But the meaner tribes of animals are made still more capable of sustaining life without food, many of them remaining in a state of torpid indifference till their prey approaches, when they jump upon and seize it. In this manner, the snake or the spider continue for several months together to subsist upon a single meal; and some of the butterfly kinds live upon little or nothing. But it is very different with man: his wants daily make their demands; and it is known that he cannot live many days without eating, drinking, and sleeping.

Hunger is a much more powerful enemy to man than watchfulness, and kills him much sooner. It may be considered as a disorder that food removes, and would quickly be fatal without its proper antidote. In fact, it is so terrible to man, that to avoid it he even encounters certain death; and, rather than endure its tortures, exchanges them for immediate destruction. However, by what I have been told, it is much more dreadful in its approaches than in its continuance; and the pains of a famishing wretch decrease as his strength diminishes. In the beginning, the desire of food is dreadful indeed, as we know by experience; for there are few who have not in some degree felt its approaches. But, after the first or second day, its tortures become less terrible, and a total insensibility at length comes kindly in to the poor wretch's assistance. I have talked with the captain of a ship, who was one of six that endured it in its extremities, and who was the only person that had not lost his senses when they received accidental relief. He assured me his pains at first were so great as to be often tempted to eat a part of one of the men who died, and which the rest of the crew actually for some time lived upon: he said that during the continuance of this paroxysm he found his pains insupportable, and was desirous at one time of anticipating that death which he thought inevitable; but his pains, he said, gradually decreased after the sixth day (for they had water in the ship, which kept them alive so long), and then he was in a state rather of languor than desire; nor did he much wish for food, except when he saw others eating; and that for a while revived his appetite, though with diminished importunity. The latter part of the time, when his health was almost destroyed, a thousand strange images rose upon his mind; and every one of his senses began to bring him wrong information. The most fragrant perfumes appeared to him to have a foetid smell; and everything he looked at took a greenish hue, and sometimes a yellow. When he was presented with food by the ship's company that took him and his men up, four of whom died shortly after, he could not help looking upon it with loathing instead of desire; and it was not till after four days that his stomach was brought to its natural tone, when the violence of his appetite returned with a sort of canine eagerness.

Thus dreadful are the effects of hunger; and yet, when we come to assign the cause that produces them, we find the subject involved in doubt and intricacy. This longing eagerness is, no doubt, given for a very obvious purpose—that of replenishing the body wasted by fatigue and perspiration. Were not men stimulated by such a pressing monitor, they might be apt to pursue other amusements with a perseverance beyond their power, and forget the useful hours of refreshment in those more tempting ones of pleasure. But hunger makes a demand that will not be refused; and indeed the generality of mankind seldom await the call.

Hunger has been supposed by some to arise from the rubbing of the coats of the stomach against each other, without having any intervening substance to prevent their painful attrition. Others have imagined that its juices, wanting their necessary supply, turn acrid, or, as some say, pungent, and thus fret its internal coats so as to produce a train of the most uneasy sensations. Boerhaave, who established his reputation in physic by uniting the conjectures of all those that preceded him, ascribes hunger to the united effect of both these causes, and asserts that the pungency of the gastric juices and the attrition of its coats against each other cause these pains, which nothing but food can remove. These juices, continuing still to be separated in the stomach, and every moment becoming more acrid, mix with the blood and infect the circulation: the circulation, being thus contaminated, becomes weaker and more contracted; and the whole nervous frame sympathising, a hectic fever, and sometimes madness, is produced; in which state the faint wretch expires. In this manner, the man who dies of hunger may be said to be poisoned by the juices of his own body; and is destroyed less by the want of nourishment than by the vitiated qualities of that which he had already taken.

However this may be, we have but few instances of men dying, except at sea, of absolute hunger—the decline of those unhappy creatures who are destitute of food on land being more slow and unperceived. These, from often being in need and as often receiving an accidental supply, pass their lives between surfeiting and repining; and their constitution is impaired by insensible degrees. Man is unfit for a state of precarious expectation. The share of provident precaution which incites him to lay up stores for a distant day becomes his torment, when totally unprovided against an immediate call. The lower race of animals, when satisfied for the instant moment, are perfectly happy; but it is otherwise with man; his mind anticipates distress, and feels the pangs of want even before it arrests him. Thus, the mind being continually harassed by the situation, it at length influences the constitution, and unfits it for all its functions. Some cruel disorder, but no way like hunger, seizes the unhappy sufferer; so that almost all those men who have thus long lived by chance, and whose every day may be considered as a happy escape from famine, are known at last to die in reality of a disorder caused by hunger; but which, in common language, is often called a "broken heart." Some of these I have known myself, when very little able to relieve them: and I have been told by a very active and worthy magistrate, that the number of such as die in London for want is much greater than one would imagine—I think he talked of two thousand in a year!

But how numerous soever those who die of hunger may be, many times greater, on the other hand, are the number of those who die by repletion. It is not the province of the present page to speculate with the physician upon the danger of surfeits, or with the moralist upon the nauseousness of gluttony; it will only be proper to observe, that as nothing is so prejudicial to health as hunger by constraint, so nothing is more beneficial to the constitution than voluntary abstinence. It was not without reason that religion enjoined this duty; since it answered the double purpose of restoring the health oppressed by luxury, and diminished the consumption of provisions, so that a part might come to the poor. It should be the business of the legislature, therefore, to enforce this divine precept; and thus, by restraining one part of mankind in the use of their superfluities, to consult for the benefit of those who want the necessities of life. The injunctions for abstinence are strict over the whole continent, and were rigorously observed, even among ourselves, for a long time after the Reformation. Queen Elizabeth, by giving her commands upon this

head the air of a political injunction, lessened in a great measure (in my opinion very unwisely) the religious force of the obligation. She enjoined that her subjects should fast from flesh on Fridays and Saturdays; but at the same time declared that this was not commanded from motives of religion, as if there were any differences in meats, but merely to favour the consumption of fish, and thus to multiply the number of mariners; and also to spare the stock of sheep, which might be more beneficial in another way. In this manner the injunction defeated its own force; and this most salutary law became no longer binding when it was supposed to come purely from man. How far it may be enjoined in the Scriptures I will not take upon me to say; but this may be asserted, that if the utmost benefit to the individual and the most extensive advantage to society serve to mark any institution as of Heaven, this of abstinence may be reckoned among the foremost.

Were we to give a history of the various benefits that have arisen from this command, and how conducive it has been to long life, the instances would fatigue with their multiplicity. It is surprising to what a great age the primitive Christians of the East who retired from persecution in the deserts of Arabia continued to live in all the bloom of health, and yet in all the rigours of abstermious discipline. Their common allowance, as we are told, for twenty-four hours was twelve ounces of bread, and nothing but water. On this simple beverage St. Anthony is said to have lived a hundred and five years; James, the hermit, a hundred and four; Arsenius, tutor to the Emperor Arcadius, a hundred and twenty; St. Epiphanius, a hundred and fifteen; Simeon, a hundred and twelve; and Rombald, a hundred and twenty. In this manner did these holy temperate men live to an extreme old age, kept cheerful by strong hopes, and healthful by moderate labour.

Abstinence which is thus voluntary may be much more easily supported than constrained hunger. Man is said to live without food for seven days—which is the usual limit assigned him; and, perhaps, in a state of constraint, this is the longest time he can survive the want of it. But in cases of voluntary abstinence, of sickness, or sleeping, he has been known to live much longer.

In the records of the tower, there is an account of a Scotchman, imprisoned for felony, who for the space of six weeks took not the least sustenance, being carefully watched during the whole time; and for this he received the king's pardon.

When the American Indians undertake long journeys, and when, consequently, a stock of provisions sufficient to support them the whole way would be more than they could carry, in order to obviate this inconvenience, instead of carrying the necessary quantity, they contrive a method of palliating their hunger by swallowing pills made of calcined shells and tobacco. These pills take away all appetite by producing a temporary disorder in the stomach; and, no doubt, the frequent repetition of this wretched expedient must at last be fatal. By this means, however, they continue several days without eating, cheerfully bearing such extremes of fatigue and watchings as would quickly destroy men bred up in a greater state of delicacy—for those arts by which we learn to obviate our necessities do not fail to unfit us for their accidental encounter.

Upon the whole, therefore, man is less able to support hunger than any other animal; and he is not better qualified to support a state of watchfulness. Indeed, sleep seems much more necessary to him than to any other creature—as, when awake, he may be said to exhaust a greater proportion of the nervous fluid, and consequently to stand in need of an adequate supply. Other animals when most awake are but little removed from a state of slumber; their feeble faculties—imprisoned in matter, and rather exerted by impulse than

deliberation—require sleep rather as a cessation from thinking. But it is otherwise with man: his ideas, fatigued with their various excursions, demand a cessation not less than the body from toil; and he is the only creature that seems to require sleep from double motives—not less for the refreshment of the mental than of the bodily frame.

There are some lower animals, indeed, that seem to spend the greater part of their lives in sleep; but, properly speaking, the sleep of such may be considered as a kind of death, and their waking a resurrection. Flies and insects are said to be asleep at a time that all the vital motions have ceased; without respiration, without any circulation of their juices, if cut in pieces they do not awake, nor does any fluid ooze out of the wound. These may be considered rather as congealed than as sleeping animals, and their rest during winter rather as a cessation from life than a necessary refreshment; but in the higher races of animals, whose blood is not thus congealed and thawed by heat, these all bear the want of sleep much better than man; and some of them continue a long time without seeming to take any refreshment from it whatsoever.

But man is more feeble—he requires its due return; and if it fails to pay the accustomed visit, his whole frame is in a short time thrown into disorder—his appetite ceases—his spirits are dejected—his pulse becomes quicker and harder—and his mind, abridged of its slumbering visions, begins to adopt waking dreams. A thousand strange phantoms arise, which come and go without his will; these, which are transient in the beginning, at last take firm possession of the mind, which yields to their dominion, and, after a long struggle, runs into confirmed madness. In that horrid state, the mind may be considered as a city without walls—open to every insult, and paying homage to every invader; every idea that then starts with any force becomes a reality; and the reason, over fatigued with its former importunities, makes no head against the tyrannical invasion, but submits to it from mere imbecility.

But it is happy for man that this state of inquietude is seldom driven to an extreme, and that there are medicines which seldom fail to give relief. However, man finds it more difficult than any other animal to procure sleep; and some are obliged to court its approaches for several hours together before they incline to rest. It is in vain that all light is excluded—that all sounds are removed—that warmth and softness conspire to invite it; the restless and busy mind still retains its former activity; and Reason, that wishes to lay down the reins, in spite of herself is obliged to maintain them. In this disagreeable state the mind passes from thought to thought, willing to lose the distinctness of perception by increasing the multitude of the images. At last, when the approaches of sleep are near, every object of the imagination begins to mix with that next it; their outlines become in a manner rounder, a part of their distinctions fades away, and sleep, that ensues, fashions out a dream from the remainder.

If, then, it should be asked from what cause this state of repose proceeds, or in what manner this binds us for several hours together, I must fairly confess my ignorance—although it is easy to tell what philosophers say upon the subject. Sleep (says Rohault) consists in a scarcity of spirits, by which the orifices or pores of the nerves in the brain, through which the spirits used to flow into the nerves, being no longer kept open by the frequency of the spirits, shut of themselves; thus the nerves, wanting a new supply of spirits, become lax, and unfit to convey any impression to the brain. All this, however, is explaining a very great obscurity by a definition somewhat more obscure; leaving, therefore, those spirits to open and shut the entrances to the brain, let us be contented with simply enumerating the effects of sleep upon the human constitution.

In sleep the whole nervous frame is relaxed, while the heart and the lungs seem more forcibly exerted. This fuller circulation produces also a swelling of the muscles—as they always find who sleep with ligatures on any part of their body. This increased circulation may also be considered as a kind of exercise, which is continued through the frame; and by this the perspiration becomes more copious, although the appetite for food is entirely taken away. Too much sleep dulls the apprehension, weakens the memory, and unfits the body for labour. On the contrary, sleep too much abridged emaciates the frame, produces melancholy, and consumes the constitution. It requires some care, therefore, to regulate the quantity of sleep, and just to take as much as will completely restore Nature without oppressing it. The poor, as Otway says, sleep little; forced by their situation to lengthen out their labour to their necessities, they have but a short interval for this pleasing and enervating refreshment. I have ever been of opinion that bodily labour demands a less quantity of sleep than mental. Labourers and artisans are generally satisfied with about seven hours; but I have known some scholars who usually slept nine, and perceived their faculties no way impaired by oversleeping.

The famous Philip Barretiere—who was considered as a prodigy of learning at the age of fourteen—was known to sleep regularly twelve hours in the twenty-four; the extreme activity of his mind when awake in some measure called for an adequate alternation of repose; and I am apt to think that when students stint themselves in this particular they lessen the waking powers of the imagination, and weaken its most strenuous exertions. Animals that seldom think, as was said, can very easily dispense with sleep; and of men, such as think least will probably be satisfied with the smallest share. A life of study, it is well known, unfits the body for receiving this gentle refreshment; the approaches of sleep are driven off by thinking: when, therefore, it comes at last, we should not be too ready to interrupt its continuance.

Sleep is, indeed, to some a very agreeable period of their existence: and it has been a question frequently asked in schools—Which is most happy, the man who was a beggar by night and a king by day, or he who is a beggar by day and a king by night? It is given in favour of the nightly monarch by him who first started the question: "For the dream," says he, "gives the full enjoyment of the dignity without its attendant inconveniences; while, on the other hand, the king, who supposes himself degraded, feels all the misery of his fallen fortune without trying to find the comforts of his humble situation. Thus, by day, both states have their peculiar distresses; but by night the exalted beggar is perfectly blessed, and the king completely miserable." All this, however, is rather fanciful than just; the pleasure dreams can give us seldom reaches to our waking pitch of happiness: the mind often, in the midst of its highest visionary satisfactions, demands of itself whether it does not owe them to a dream, and frequently awakes with the reply.

But it is seldom—except in cases of the highest delight or the most extreme uneasiness—that the mind has power thus to disengage itself from the dominion of fancy. In the ordinary course of its operations it submits to those numberless phantastic images that succeed each other, and which, like many of our waking thoughts, are generally forgotten. Of these, however, if any, by their continuance, affect us strongly, they are then remembered; and there have been some who felt their impressions so strongly as to mistake them for realities, and to rank them among the past actions of their lives.

There are others upon whom dreams seem to have a very different effect; and who, without seeming to remember their impressions the next morning, have yet shown by their actions during sleep that they were very

powerfully impelled by their dominion. We have numberless instances of such persons who, while asleep, have performed many of the ordinary duties to which they have been accustomed when waking, and, with a ridiculous industry, have completed by night what they failed doing by day. We are told in the German Ephemerides of a young student who, being enjoined a severe exercise by his tutor, went to bed despairing of accomplishing it. The next morning waking, to his great surprise he found the task fairly written out, and finished in his own hand-writing. He was at first, as the account has it, induced to ascribe this strange production to the operation of an infernal agent; but his tutor, willing to examine the affair to the bottom, set him another exercise still more severe than the former, and took precautions to observe his conduct the whole night. The young gentleman, upon being so severely tasked, felt the same inquietude that he had done on the former occasion; went to bed gloomy and pensive, pondering on the next day's duty, and, after some time, fell asleep. But shortly after, his tutor, who continued to observe him from a place that was concealed, was surprised to see him get up, and very deliberately go to the table, where he took out pen, ink, and paper, drew himself a chair, and sat very methodically to thinking: it seems that his being asleep only served to strengthen the powers of his imagination; for he very quickly and easily went through the task assigned him, put his chair aside, and then returned to bed to take out the rest of his nap. What credit we are to give to this account I will not pretend to determine; but this may be said, that the book from whence it is taken has some good marks of veracity—for it is very learned and very dull, and is written in a country noted, if not for truth, at least for want of invention.

The ridiculous history of Arlotto is well known, who has had a volume written containing a narrative of the actions of his life, not one of which was performed while he was awake. He was an Italian Franciscan friar, extremely rigid in his manners, and remarkably devout and learned in his daily conversation. By night, however, and during his sleep, he played a very different character from what he did by day, and was often detected in very atrocious crimes. He was at one time detected in actually attempting a rape, and did not awake till the next morning, when he was surprised to find himself in the hands of justice. His brothers of the convent often watched him while he went very deliberately into the chapel, and there attempted to commit sacrilege. They sometimes permitted him to carry the chalice and the vestments away into his own chamber, and the next morning amused themselves at the poor man's consternation for what he had done. But of all his sleeping transgressions, that was the most ridiculous in which he was called to pray for the soul of a person departed. Arlotto, after having devoutly performed his duty, retired to a chamber which was shown him to rest; but there he had no sooner fallen asleep, than he began to reflect that the dead body had got a ring upon one of the fingers, which might be useful to him; accordingly, with a pious resolution of stealing it, he went down, undressed as he was, into a room full of women, and, with great composure, endeavoured to seize the ring. The consequence was that he was taken before the Inquisition for witchcraft; and the poor creature had like to have been condemned, till his peculiar character accidentally came to be known; however, he was ordered to remain for the rest of life in his own convent, and upon no account whatsoever to stir abroad.

What are we to say of such actions as these, or how account for this operation of the mind in dreaming? It would seem that the imagination by day as well as by night is always employed, and that often against our wills it intrudes where it is least commanded or desired. While awake and in health this busy principle

cannot much delude us; it may build castles in the air, and raise a thousand phantoms before us; but we have every one of the senses alive to bear testimony to its falsehood. Our eyes show us that the prospect is not present; our hearing and our touch depose against its reality; and our taste and smelling are equally vigilant in detecting the impostor. Reason, therefore, at once gives judgment upon the cause; and the vagrant intruder, Imagination, is imprisoned or banished from the mind. But in sleep it is otherwise; having, as much as possible, put our senses from their duty—having closed the eyes from seeing, and the ears, taste, and smelling from their peculiar functions, and having diminished even the touch itself by all the arts of softness—the imagination is then left to riot at large, and to lead the understanding without an opposer. Every incurative idea then becomes a reality; and the mind, not having one power that can prove the illusion, takes them for truths. As in madness, the senses, from struggling with the imagination, are at length forced to submit, so in sleep they seem for a while soothed into the like submission; the smallest violence exerted upon any one of them, however, rouses all the rest in their mutual defence; and the imagination, that had for a while told its thousand falsehoods, is totally driven away, or only permitted to pass under the custody of such as are every moment ready to detect its imposition.

## CHAP. VII.

### OF SEEING.

Having mentioned the senses as correcting the errors of the imagination, and as forcing it in some measure to bring us just information, it will naturally follow that we should examine the nature of those senses themselves; we shall thus be enabled to see how far they also impose on us, and how far they contribute to correct each other. Let it be observed, however, that in this we are neither giving a treatise of optics or phonics, but a history of our own perceptions; and to those we chiefly confine ourselves.

The eyes very soon begin to be formed in the human embryo, and in the chicken also. Of all the parts which the animal has double the eyes are produced the soonest, and appear the most prominent. It is true, indeed, that in viviparous animals, and particularly in man, they are not so large in proportion at first as in the oviparous kinds; nevertheless, they are more speedily developed when they begin to appear than any other parts of the body. It is the same with the organ of hearing; the little bones that compose the internal parts of the ear are entirely formed before the other bones, though much larger, have acquired any part of their growth or solidity—hence it appears that those parts of the body which are furnished with the greatest quantity of the nerves are the first in forming. Thus the brain and the spinal-marrow are the first seen begun in the embryo; and in general it may be said, that wherever the nerves go or send their branches in great numbers, there the parts are soonest begun, and the most completely finished.

If we examine the eyes of a child some hours, or even some days, after its birth, it will be easily discerned that it as yet makes no use of them. The humours of the organ not having acquired a sufficient consistence, the rays of light strike but confusedly upon the retina, or expansion of the nerves at the back of the eye. It is not till about a month after they are born that children fix them upon subjects, for before that time they turn them indiscriminately everywhere, without appearing to be affected by any. At six or seven weeks old they plainly discover a choice in the objects of their attention;

they fix their eyes upon the most brilliant colours, and seem peculiarly desirous of turning them towards the light. Hitherto, however, they only seem to fortify the organ for seeing distinctly; but they have still many illusions to correct.

The first great error in vision is that the eye inverts every object; and it in reality appears to the child, until the touch has served to undeceive it, turned upside down. A second error in vision is, that every object appears double. The same object forms itself distinctly upon each eye, and is consequently seen twice. This error, also, can only be corrected by the touch; and although in reality every object we see appears inverted and double, yet the judgment and habit have so often corrected the sense that we no longer submit to its imposition, but see every object in its just position the very instant it appears. Were we, therefore, deprived of feeling, our eyes would not only misrepresent the situation, but also the number of all things round us.

To convince us that we see objects inverted, we have only to observe the manner in which images are represented coming through a small hole in a dark room. If such a small hole be made in a dark room, so that no light can come in but through it, all the objects without will be painted on the wall behind, but in an inverted position, and their heads downwards; for as all the rays which pass from the different parts of the objects without cannot enter the hole in the same extent which they had in leaving the object, since, if so, they would require the aperture to be as large as the object; and as each part and every point of the object sends forth the image of itself on every side, and the rays which form these images pass from all points of the object as from so many centres, so such only can pass through the small aperture as come in opposite directions. Thus the little aperture becomes a centre for the entire object, through which the rays from the upper parts as well as from the lower parts of it pass in converging directions; and consequently they must cross each other in the central point, and thus paint the objects behind upon the wall in an inverted position.

It is in like manner easy to conceive that we see all objects double, whatever our present sensations may tell us to the contrary; for, to convince us of this, we have only to compare the situation of any one object on shutting one eye, and then compare the same situation by shutting the other. If, for instance, we hold up a finger and shut the right eye, we shall find it hide a certain part of the room; if again reshutting the other eye, we shall find that part of the room visible, and the finger seeming to cover a part of the room that had been visible before. If we open both eyes, however, the part covered will appear to lie between the two extremes. But the truth is, we see the object our finger had covered, one image of it to the right and the other to the left, but from habit suppose that we see but one image placed upon both—our sense of feeling having corrected the errors of sight. And thus, also, if instead of two eyes we had two hundred, we should fancy the objects increased in proportion, until one sense had corrected the errors of another.

The having two eyes might thus be said to be rather an inconvenience than a benefit, since one eye would answer the purposes of sight as well, and be less liable to illusion. But it is otherwise; two eyes greatly contribute, if not to distinct, at least to extensive vision. When an object is placed at a moderate distance, by the means of both eyes we see a larger share of it than we possibly could with one—the right eye seeing a greater portion of its right side, and the left eye of its correspondent side. Thus both eyes in some measure see round the object; and it is this that gives it in nature that bold relieve or swelling with which they appear, and which no painting, how exquisite soever, can attain to. The painter must be contented with shading on a flat surface,

but the eyes in observing Nature do not behold the shading only, but a part of the figure also lies behind these very shadings, which gives it that swelling which painters so ardently desire, but can never fully imitate.

There is another defect which either of the eyes, taken singly, would have, but which is corrected by having the organ double. In either eye there is a point which has no vision whatsoever; so that if one of them only is employed in seeing, there is a part of the object to which it is always totally blind. This is that part of the optic nerve where its vein and artery run; which being insensible, that point of the object that is painted there must continue unseen. To be convinced of this, we have only to try a very easy experiment. If we take three black patches and stick them upon a white wall, about a foot distant from each other, each about as high as the eye that is to observe them; then retiring six or seven feet back, and shutting one eye, by trying for some time, we shall find that while we distinctly behold the black spots that are to the right and left, that which is in the middle remains totally unseen; or, in other words, when we bring that part of the eye where the optic artery runs to fall upon the object, it will then become invisible. This defect, however, in either eye is always corrected by both, since the part of the object that is unseen by one will be very distinctly perceived by the other.

Besides the former defects, we can have no idea of distances from the sight without the help of touch. Naturally every object we see appears to be within our eyes; and a child who has as yet made but little use of the sense of feeling must suppose that everything it sees makes a part of itself. Such objects are only seen more or less bulky as they approach or recede from its eyes; so that a fly that is near will appear larger than an ox at a distance. It is experience alone that can rectify this mistake; and a long acquaintance with the real size of every object quickly assures us of the distance at which it is seen. The last man in a file of soldiers appears in reality much less, perhaps ten times more diminutive, than the man next to us; however, we do not perceive this difference, but continue to think him of equal stature; for the numbers we have seen thus lessened by distance, and have found by repeated experience to be of the natural size, when we come closer instantly corrects the sense, and every object is perceived with nearly its natural proportion. But it is otherwise if we observe objects in such situations as we have not had sufficient experience to correct the errors of the eye; if, for instance, we look at men from the top of a high steeple, they in that case appear very much diminished, as we have not had a habit of correcting the sense in that position.

Although a small degree of reflection will serve to convince us of the truth of these positions, it may not be amiss to strengthen them by an authority which cannot be disputed. Mr. Cheselden having couched a boy of thirteen of a cataract who had hitherto been blind, and thus at once having restored him to sight, curiously marked the progress of his mind upon that occasion. This youth, though he had been till then incapable of seeing, yet was not totally blind, but could tell day from night, as persons in his situation always may. He could also, with a strong light, distinguish black from white, and either from the vivid colour of scarlet; however, he saw nothing of the form of bodies; and without a bright light not even colours themselves. He was at first couched only in one of his eyes; and when he saw for the first time, he was so far from judging of distances, that he supposed his eyes touched every object that he saw, in the same manner as his hands might be said to feel them. The objects that were most agreeable to him were such as were of plain surfaces and regular figures; though he could as yet make no judgment whatever of their different forms, nor give a rea-

son why one pleased him more than another. Although he could form some idea of colours during his state of blindness, yet that was not sufficient to direct him at present; and he could scarcely be persuaded that the colours he now saw were the same with those he had formerly conceived such erroneous ideas of. He delighted most in green; but black objects, as if giving him an idea of his former blindness, he regarded with horror. He had, as was said, no idea of forms, and was unable to distinguish one object from another, though never so different. When those things were shown him which he had been formerly familiarized to by his feelings, he beheld them with earnestness, in order to remember them a second time; but, as he had too many to recollect at once, he forgot the greatest number; and for one he could tell after seeing, there was a thousand he was totally unacquainted with. He was very much surprised to find that those things and persons he loved best were not the most beautiful to be seen; and even testified displeasure in not finding his parents so handsome as he conceived them to be. It was near two months before he could find that a picture resembled a solid body. Till then he only considered it as a flat surface, variously shadowed; but when he began to perceive that these kind of shadings actually represented human beings, he then began to examine by his touch whether they had not the usual qualities of such bodies, and was greatly surprised to find what he expected a very unequal surface to be smooth and even. He was then shown a miniature picture of his father, which was contained in his mother's watch-case, and he readily perceived the resemblance; but asked with great astonishment how so large a face could be contained in so small a compass. It seemed as strange to him as if a bushel was contained in a pint vessel. At first he could bear but a very small quantity of light, and he saw every object much greater than the life; but, in proportion as he saw objects that were really large, he seemed to think the former were diminished; and although he knew the chamber where he was contained in the house, yet until he saw the latter he could not be brought to conceive how a house could be larger than a chamber. Before the operation he had no great expectations from the pleasure he should receive from a new sense; he was only excited by the hopes of being able to read and write; he said, for instance, that he could have no greater pleasure in walking in the garden with his sight than he had without it, for he walked there at his ease, and was acquainted with all the walks. He remarked, also with great justice, that his former blindness gave him one advantage over the rest of mankind, which was that of being able to walk in the night with confidence and security. But when he began to make use of his new sense he seemed transported beyond measure. He said that every new object was a new source of delight, and that his pleasure was so great as to be past expression. About a year after this he was brought to Epcom, where there is a very fine prospect, with which he seemed greatly charmed; and he called the landscape before him a new method of seeing. He was couched in the other eye a year after the former, and the operation succeeded remarkably well. When he saw with both eyes, he said that objects appeared to him twice as large as when he saw but with one; however, he did not see them doubled, or at least he showed no signs as if he saw them so. Mr. Cheselden mentions instances of many more that were restored to sight in this manner; they all seemed to concur in their perceptions with this youth, and they all seemed particularly embarrassed in learning how to direct their eyes to the objects they wished to observe.

In this manner it is that our feeling corrects the senses of seeing, and that objects which appear of very different sizes at different distances are all reduced by experience to their natural standard. But not the feeling only, but

also the colour and brightness of the object, contribute in some measure to assist us in forming an idea of the distance at which it appears. Those which we see most strongly marked with light and shade we readily know to be nearer than those on which the colours are more faintly spread, and that in some measure take a part of their hue from the air between us and them. Bright objects, also, are seen at a greater distance than such as are obscure, and most probably for this reason—that, being less similar in colour to the air that interposes, their impressions are less effaced by it, and they continue more distinctly visible. Thus a black and distant object is not seen so far off as a bright and glittering one, and a fire by night is seen much farther off than by day.

The power of seeing objects at a distance is seldom equal in both eyes. When this inequality is in any great degree, the person so circumstanced then makes use only of one eye, shutting that which sees the least, and employing the other with all its power. And hence proceeds that awkward look which is known by the name of “strabism.”

There are many reasons to induce us to think that such as are near-sighted see objects larger than other persons; and yet the contrary is most certainly true, for they see them less. Mr. Buffon informs us that he himself was short-sighted, and that his left eye was stronger than his right. He has very frequently experienced upon looking at an object, such as the letters of a book, that they appear less to the weakest eye; and that when he placed the book so as that the letters appeared double, the images of the left eye, which was strongest, were larger than those of the right, which was more feeble. He has examined several others who were in similar circumstances, and has always found that the best eye saw every object the largest. This he ascribes to habit; for near-sighted people being accustomed to come close to the object, and view but a small part of it at a time, the habit ensues, when the whole of an object is seen, and it appears less to them than to others.

Infants, having their eyes less than adults, must see objects also smaller in proportion; for the image formed on the back of the eye will be large as the eye is capacious; and infants, having it not so great, cannot have so large a picture of the object. This may be a reason also why they are unable to see so distinctly or at such distances as persons arrived at maturity.

Old men, on the contrary, see bodies close to them very indistinctly, but bodies at a great distance from them with more precision; and this may happen from an alteration in the coats or humours of the eye, and not, as is supposed, from their diminution. The cornea, for instance, may become too rigid to adapt itself, and take a proper convexity for seeing minute objects; and its very flatness will be sufficient to fit it for distant vision.

When we cast our eyes upon an object extremely brilliant, or when we fix and detain them too long upon the same object, the organ is hurt and fatigued, its vision becomes indistinct, and the image of the body, which has thus too violently or too perseveringly employed us, is painted upon everything we look at, and mixes with every object that occurs. And this is an obvious consequence of the eye taking in too much light, either immediately or by reflection. Every body exposed to the light for a time drinks in a quantity of its rays, which, being brought into darkness, it cannot instantly discharge. Thus the hand, if it be exposed to broad day-light for some time, and then immediately snatched into a dark room, will appear still luminous; and it will be some time before it is totally darkened. It is thus with the eye, which, either by an instant gaze at the meridian sun or a steady continuance upon some less brilliant object, has taken in too much light; its humours are for a while unfit for vision, until that be discharged and room made for rays of a milder nature.

How dangerous the looking upon bright and luminous objects is to the sight, may be easily seen from such as live in countries covered for most part of the year with snow, who become generally blind before their time. Travellers who cross these countries are obliged to wear a crape to save their eyes, which would otherwise be rendered totally unserviceable; and it is equally dangerous in the sandy plains of Africa. The reflection of the light is there so strong, that it is impossible to sustain the effect without incurring the danger of losing one's sight entirely. Such persons, therefore, as read or write for any continuance should choose a moderate light, in order to save their eyes; and although it may seem sufficient at first, the eye will accustom itself to the shade by degrees, and be less hurt by the want of light than the excess.

It is indeed surprising how far the eye can accommodate itself to darkness, and make the best of a gloomy situation. When first taken from the light and brought into a dark room, all things disappear; or, if anything is seen, it is only the remaining radiations that still continue in the eye. But after a very little time, when these are spent, the eye takes advantage of the smallest ray that happens to enter; and this alone would in time serve for many of the purposes of life. There was a gentleman of great courage and understanding, who was a major under King Charles I. This unfortunate man, sharing in his master's misfortunes, and being forced abroad, ventured at Madrid to do his king a signal service, but unluckily failed in the attempt. In consequence of this he was instantly ordered to a dark and dismal dungeon, into which the light never entered, and into which there was no opening but by a hole at the top, down which the keeper put his provisions, and presently closed it again on the other side. In this manner the unfortunate loyalist continued for some weeks, distressed and disconsolate; but at last he began to think he saw some little glimmering of light. This internal dawn seemed to increase from time to time, so that he could not only discover the parts of his bed and such other large objects, but at length he even began to perceive the mice that frequented his cell, and saw them as they ran about the floor eating the crumbs of bread that happened to fall. After some months' confinement he was at last set free; but such was the effect of the darkness upon him that he could not for some days venture to leave his dungeon, but was obliged to accustom himself by degrees to the light of the day.

## CHAP. VIII.

### OF HEARING.

As the sense of hearing as well as of sight gives us notice of remote objects, so like that it is subject to similar errors, being capable of imposing on us upon all occasions where he cannot rectify it by the sense of feeling. We can have from it no distinct intelligence of the distance from whence a sounding body is heard; a great noise far off and a small one very near produce the same sensation; and, unless we receive information from some other sense, we can never distinctly tell whether the sound be a great or a small one. It is not till we have learned by experience that the particular sound which is heard is of a peculiar kind; then we can judge of the distance from whence we hear it. When we know the tone of the bell, we can then judge how far it is from us.

Every body that strikes against another produces a sound, which is simple, and but one in bodies which are not elastic, but which is often repeated in such as are. If we strike a bell or a stretched string, for instance, which are both elastic, a single blow produces a sound,

which is repeated by the undulations of the sonorous body, and which is multiplied as often as it happens to undulate or vibrate. These undulations each strike their own peculiar blow; but they succeed so fast, one behind the other, that the ear supposes them one continued sound; whereas in reality they make many. A person who should for the first time hear the toll of a bell, would very probably be able to distinguish these breaks of sound; and, in fact, we ourselves can readily perceive an intension and remission in the sound.

In this manner, sounding bodies are of two kinds; those unelastic ones, which, being struck, return but a single sound; and those more elastic, returning a succession of sound, which, uniting together, form a tone. This tone may be considered as a great number of sounds all produced one after the other by the same body, as we find in a bell or the string of a harpsichord, which continues to sound for some time after it is struck. A continuing tone may be also produced from a nonelastic body by repeating the blow quick and often, as when we beat a drum, or when we draw a bow along the strings of a fiddle.

Considering the subject in this light, if we should multiply the number of blows, or repeat them at quicker intervals upon the sounding body, as upon the drum, for instance, it is evident that this will have no effect in altering the tone; it will only make it either more even or more distinct. But it is otherwise if we increase the force of the blow; if we strike the body with double weight this will produce a tone twice as loud as the former. If, for instance, I strike a table with a switch, this will be very different from the sound produced by striking it with a cudgel. Hence, therefore, we may infer that all bodies give a louder and graver tone, not in proportion to the number of times they are struck, but in proportion to the force that strikes them. And if this be so, those philosophers who make the tone of a sonorous body—of a bell or the string of a harpsichord, for instance—to depend upon the number only of its vibrations and not on the force, have mistaken what is only an effect for a cause. A bell or an elastic string can only be considered as a drum beaten; and the frequency of the blows can make no alteration whatever in the tone. The largest bells and the longest and thickest strings have the most forceful vibrations; and therefore their tones are the most loud and the most grave.

To know the manner in which sounds thus produced become pleasing; it must be observed, no one continuing tone, how loud or swelling soever, can give us satisfaction: we must have a succession of them, and those in the most pleasing proportion. The nature of this proportion may be thus conceived. If we strike a body incapable of vibration with a double force, or, what amounts to the same thing, with a double mass of matter, it will produce a sound that will be doubly grave. Music has been said by the ancients to have been first invented from the blows of different hammers on an anvil. Suppose, then, we strike on an anvil with a hammer of one pound weight, and again with a hammer of two pounds, it is plain that the two-pound hammer will produce a sound twice as grave as the former. But if we strike with a two-pound hammer and then with a three-pound, it is evident that the latter will produce a sound one-third more grave than the former. If we strike the anvil with a three-pound hammer and then with a four-pound, it will likewise follow that the latter will be a quarter part more grave than the former. Now, in the comparing between all these sounds, it is obvious that the difference between one and two is more easily perceived than between two and three, three and four, or any numbers succeeding in the same proportion. The succession of sounds will be therefore pleasing in proportion to the ease with which they may be distinguished. That sound which is double the former, or, in other words, the octave to the preceding tone, will of all others be the most

pleasing harmony. The next to that, which is as two to three, or, in other words, the third, will be most agreeable. And thus, universally, those sounds whose difference may be most easily compared are the most agreeable.

Musicians, therefore, have contented themselves with seven different proportions of sound, which are called "notes," and which sufficiently answer all the purposes of pleasure. Not but that they might adopt a greater diversity of proportions; and some have actually done so; but in these the differences of the proportion are so imperceptible, that the ear is more fatigued than pleased in making the distinction. In order, however, to give variety, they have admitted half-tones; but in all the countries where music is yet in its infancy they have rejected such; and they can find music in none but the obvious ones. The Chinese, for instance, have neither flats nor sharps in their music; but the intervals between their other notes are in the same proportion with ours.

Many more barbarous nations have their peculiar instruments of music; and what is remarkable, the proportion between their notes is in all the same as in ours. This is not the place for entering into the nature of these sounds, their effects upon the air, or their consonances with each other. We are not now giving a history of sound, but of human perception.

All countries are pleased with music; and if they have not skill enough to produce harmony, at least they seem willing to substitute noise. Without all question, noise alone is sufficient to operate powerfully on the spirits; and, if the mind be already predisposed to joy, I have seldom found noise fail of increasing it into rapture. The mind feels a kind of distracted pleasure in such powerful sounds, braces up every nerve, and riots in the excess. But, as in the eye an immediate gaze upon the sun will disturb the organ, so in the ear a loud, unexpected noise disorders the whole frame, and sometimes disturbs the sense ever after. The mind must have time to prepare for the expected shock, and to give its organs the proper tension for its arrival.

Musical sounds, however, seem of a different kind. Those are generally most pleasing which are most unexpected. It is not from bracing up the nerves, but from the grateful succession of the sounds, that these become so charming. There are few, how indifferent soever, but have at times felt their pleasing impression; and perhaps even those who have stood out against the powerful persuasion of sounds only wanted the proper tune or the proper instrument to allure them.

The ancients give us a thousand strange instances of the effects of music upon men and animals. The story of Arion's harp, that attracted the dolphins to the ship's side, is well known; and what is remarkable, Schottæus assures us that he saw a similar instance of fishes being allured by music. They tell us of diseases that have been cured, unchastity corrected, seditions quelled, passions removed, and sometimes excited even to madness. Dr. Wallis has endeavoured to account for these surprising effects by ascribing them to the novelty of the art. For my own part, I can scarce hesitate to impute them to the exaggeration of their writers. They are as hyperbolic in the effects of their oratory; and yet we well know there is nothing in the orations they have left us capable of exciting madness, or of raising the mind to that ungovernable degree of fury which they describe. As they have exaggerated, therefore, in one instance, we may naturally suppose that they have done the same in the other; and, indeed, from the few remains we have of their music, collected by Meibomius, one might be apt to suppose there was nothing very powerful in what is lost. Nor does any one of the ancient instruments—such as we see them represented in statues—appear comparable to our fiddle.

However this be, we have many odd accounts, not only among them but also among the moderns, of the

power of music; and it must not be denied but that, on some particular occasions, musical sounds may have a very powerful effect. I have seen all the horses and cows in a field, amounting to more than a hundred, gather round a person that was blowing the French horn, and seemed to testify an awkward kind of satisfaction. Dogs are well known to be sensible of the different tones in music; and I have sometimes heard them sustain a very ridiculous part in a concert where their assistance was neither expected nor desired.

We are told of Henry IV. of Denmark, that, being one day desirous of trying in person whether a musician, who boasted that he could excite men to madness, was not an impostor, he submitted to the operations of his skill; but the consequence was much more terrible than the king expected—for, becoming actually mad, he killed four of his attendants in the midst of his transports. A contrary effect of music we have in the cure of a madman of Alais, in France. This man, who was a dancing-master, after a fever of five days, grew furious, and so ungovernable that his hands were obliged to be tied to his sides: what at first was rage in a short time was converted into silent melancholy, which no arts could exhilarate nor no medicines remove. In this sullen and dejected state an old acquaintance accidentally came to inquire after his health; he found him sitting up in bed, tied, and totally regardless of every external object round him. Happening, however, to take up a fiddle that lay in the room, and playing a favourite air, the poor madman instantly seemed to brighten up at the sound; from a recumbent posture he began to sit up; and, as the musician continued playing, the patient seemed desirous of dancing to the sound; but he was tied, and incapable of leaving his bed, so that he could only humour the tune with his head, and that part of his arms which were at liberty. Thus the other continued playing, and the dancing-master practised his own art as far as he was able, for about a quarter of an hour, when suddenly falling into a deep sleep, in which his disorder came to a crisis, he awoke perfectly recovered.

A thousand other instances might be added, equally true; let it suffice to add one more, which is not true—I mean that of the tarantula. Every person who has been in Italy now well knows that the bite of this animal and its being cured by music is all a deception. When strangers come into that part of Italy the country people are ready enough to take money for dancing to the tarantula. A friend of mine had a servant who suffered himself to be bitten; the wound, which was little larger than the puncture of a pin, was uneasy for a few hours, and then became well without any further assistance. Some of the country people, however, still make a tolerable livelihood of the credulity of strangers, as the musician finds his account in it no less than the dancer.

Sounds, like light, are not only extensively diffused but are frequently reflected. The laws of this reflection, it is true, are not so well understood as those of light; all we know is, that sound is principally reflected by hard bodies—and their being hollow also sometimes increases the reverberation. No art, however, can make an echo; and some who have bestowed great labour and expense upon such a project have only erected shapeless buildings, whose silence was a mortifying lecture on their presumption.

The internal cavity of the ear seems to be fitted up for the purposes of echoing sound with the greatest precision. This part is fashioned out in the temporal bone like a cavern cut into a rock. In this the sound is repeated and articulated, and, as some anatomists tell us (for we have as yet but very little knowledge on the subject), is beaten against the tympanum or drum of the ear, which moves four little bones joined thereto; these move and agitate the internal air which lies on the other

side; and, lastly, this air strikes and affects the auditory nerves, which carry the sound to the brain.

One of the most common disorders in old age is deafness—which probably proceeds from the rigidity of the nerves in the labyrinth of the ear. This disorder also sometimes proceeds from a stoppage of the wax, which art may easily remedy. In order to know whether the defect be an internal or an external one, let the deaf person put a repeating watch into his mouth, and if he hears it strike, he may be sure that his disorder proceeds from an external cause, and is in some measure curable; for there is a passage from the ears into the mouth by what anatomists call the “eustachian tube,” and by this passage people often hear sounds when they are utterly without hearing through the larger channel; and this is also the reason that we often see persons who listen with great attention do so with their mouths open, in order to catch all the sound at every aperture.

It often happens that persons hear differently with one ear from the other; and it is generally found that these have what is called by musicians a “bad ear.” Mr. Buffon, who has made many trials upon persons of this kind, always found that their defect in judging properly of sounds proceeded from the inequality of their ears; and receiving by both at the same time unequal sensations, they form an unjust idea. In this manner, as those people hear false, they also, without knowing it, sing false. Those persons also frequently deceive themselves with regard to the side from whence the sound comes, generally supposing the noise to come on the part of the best ear.

Such as are hard of hearing find the same advantage in the trumpet made for this purpose that short-sighted persons do from glasses. These trumpets might be easily improved, so as to increase sounds in the same manner that the telescope does objects; however, they could be used to advantage only in a place of solitude and stillness, as the neighbouring sounds would mix with the more distant, and the whole would produce in the ear nothing but tumult and confusion.

Hearing is a much more necessary sense to man than to animals. With these it is only a warning against danger, or an encouragement to mutual assistance. In man it is the source of most of his pleasures; and without which the rest of his senses would be of little benefit. A man born deaf must necessarily be dumb, and his whole sphere of knowledge must be bounded only by sensual objects. We have an instance of a young man who, being born deaf, was restored at the age of twenty-four to perfect hearing.

A young man of the town of Chartres, between the age of twenty-three and twenty-four, the son of a tradesman, and deaf and dumb from his birth, began to speak all of a sudden to the great astonishment of the whole town. He gave them to understand that, about three or four months before, he had heard the sound of the bells for the first time, and was greatly surprised at this new and unknown sensation. After some time a kind of water issued from his left ear, and he then heard perfectly well with both. During these three months he was sedulously employed in listening without saying a word, and accustoming himself to speak softly (so as not to be heard) the words pronounced by others. He laboured hard, also, in perfecting himself in the pronunciation and in the ideas attached to every sound. At length, having supposed himself qualified to break silence, he declared that he could now speak, although as yet but imperfectly. Soon after, some able divines questioned him concerning his ideas of his past state; and principally with respect to God, his soul, and the morality or turpitude of actions. The young man, however, had not driven his solitary speculations into that channel. He had gone to mass, indeed, with his parents—had learned to sign himself with the cross—to kneel down, and assume all the grimaces of a man

that was praying; but he did all this without any manner of knowledge of the intention or the cause; he saw others do the like, and that was enough for him; he knew nothing even of death—the idea never entered into his head; he led a life of pure animal instinct; entirely taken up with sensible objects and such as were present, he did not seem even to make as many reflections upon these as might reasonably be expected from his improving situation: and yet the young man was not in want of understanding; but the understanding of a man deprived of all commerce with others is so very confined, that the mind is in some measure totally under the control of its immediate sensations.

Notwithstanding, it is very possible to communicate ideas to deaf men with which they were previously unacquainted, and even give them very precise notions of some abstract subjects, by means of signs and letters. A person born deaf may by time and sufficient pains be taught to read and write, to speak, and, by the motions of the lips, to understand what is said to him; however, it is probable that, as most of the motions of speech are made within the mouth by the tongue, the knowledge from the motion of the lips is but very confined: nevertheless, I have conversed with a gentleman thus taught, and in all the commonly-occurring questions and the usual salutations he was quite cognizant merely by watching the motion of the lips alone. When I ventured to speak for a short continuance he was totally at a loss, although he understood the subject when written extremely well. Persons taught in this manner were at first considered as prodigies; but there have been so many instances of success of late, and so many are skilful in the art of instructing in this way, that, though still a matter of some curiosity, it ceases to be an object of wonder.

## CHAP. IX

### OF SMELLING, FEELING, AND TASTING.

An animal may be said to fill up that sphere which he can reach by his senses, and is actually large in proportion to the sphere to which its organ extends. By sight, man's enjoyments are diffused into a wide circle; that of hearing, though less widely diffused, nevertheless extends his powers; the sense of smelling is more contracted still; and the taste and touch are the most confined of all. Thus man enjoys very distant objects, but with one sense only; more nearly he brings two senses at once to bear upon them; his sense of smelling assists the other two, at his own distance; and of such objects, as a man, he may be said to be in perfect possession.

Each sense, however, the more it acts at a distance the more capable it is of making combinations, and is consequently the more improveable. Refined imaginations and men of strong minds therefore take more pleasure in improving the delights of the distant senses than enjoying such as are scarce capable of improvement.

By combining the objects of the extensive senses, all the arts of poetry, painting, and harmony have been discovered; but the closer senses, if I may so call them, such as smelling, tasting, and touching, are in some measure as simple as they are limited, and admit of little variety. The man of imagination makes a great and artificial happiness by the pleasure of altering and combining; the sensualist just stops where he began, and cultivates only those pleasures which he cannot improve. The sensualist is contented with those enjoyments that are already made to his hand; but the man of pleasure is best pleased with growing happiness.

Of all the senses, perhaps, there is not one in which man is more inferior to other animals than in that of

smelling. With man, it is a sense that acts in a narrow sphere, and disgusts almost as frequently as it gives him pleasure. With many other animals it is diffused to a very great extent, and never seems to offend them. Dogs not only trace the steps of other animals, but also discover them by the scent at a very great distance; and while they are thus exquisitely sensible of all smells, they seem no way disgusted by any.

But although this sense is in general so very inferior in man, it is much stronger in those nations that abstain from animal food than it is among Europeans. The Brahmins of India have a power of smelling, as I am informed, equal to what it is in most other creatures. They can smell the water which they drink, which to us seems quite inodorous; and they have a word in their language which denotes a country of fine water. We are also told that the Negroes of the Antilles, by the smell alone, can distinguish between the footsteps of a Frenchman and a Negro. It is possible, therefore, that we may dull this organ by our luxurious way of living, and sacrifice to the pleasures of taste those which might be received from perfume.

However, it is a sense that we can in some measure dispense with; and I have known many that wanted it entirely but very little inconvenienced from its loss. In a state of nature it is said to be useful in guiding us to proper nourishment, and deterring us from that which is unwholesome; but in our present situation such information is but little attended to. In fact, the sense of smelling frequently gives us false intelligence. Many things that have a disagreeable odour are, nevertheless, wholesome and pleasant to the taste; and such as make eating an art seldom think a meal fit to please the appetite till it begins to offend the nose. On the other hand, there are many things that smell most gratefully and yet are noxious, and fatal to the constitution. Some physicians think that perfumes in general are unwholesome—that they relax the nerves, produce head-aches, and even retard digestion. The machinel apple, which is known to be deadly poison, is possessed of the most grateful odour. Some of those mineral vapours that are often found fatal to the stomach smell like the sweetest flowers, and continue thus to flatter till they destroy. This sense, therefore, as it would seem, was never meant to direct us in the choice of food, but appears rather as an attendant than a necessary pleasure.

Indeed, if we examine the natives of different countries, or even the different natives of the same, we shall find no pleasure in which they differ so widely as that of smelling. Some persons are pleased with the smell of a rose; while I have known others that could not abide to have it approach them. The savage nations are highly delighted with the smell of assafoetida, which is to us the most nauseous stink in nature. It would in a manner seem that our delight in perfumes was made by habit, and that a very little industry could bring us totally to invert the perception of odours.

Thus much is certain, that many bodies which at one distance are an agreeable perfume, when nearer are a most ungrateful odour. Musk and ambergris, in small quantities, are considered by most persons as highly fragrant; and yet, when in larger masses, their scent is insufferable. From a mixture of two bodies, each of which is of itself void of all smell, a very powerful smell may be drawn. Thus, by grinding quick-lime with sal-ammoniac may be produced a very foetid mixture. On the contrary, from a mixture of two bodies that are separately disagreeable a very pleasant aromatic odour may be gained. A mixture of aqua-fortis with spirits of wine produces this effect. But not only the alterations of bodies by each other, but the smallest change in us, makes a great alteration in this sense, and not unfrequently totally deprives us of it. A slight cold often prevents us from smelling, and as often changes the nature of odours. Some persons, from disorder, retain

an insurable aversion to those smells which pleased them most before; and many have been known to have an antipathy to some animals whose presence they instantly perceive by the smell. From all this, therefore, the sense of smelling appears to be an uncertain monitor—easily disordered, and not much missed when totally wanting.

The sense most nearly allied to smelling is that of tasting. This some have been willing to consider merely as a nicer kind of touch, and have undertaken to account in a very mechanical manner for the difference of flavours. "Such bodies," say they, "as are pointed, happening to be applied to the papillæ of the tongue, excite a very powerful sensation, and give us the idea of saltiness. Such, on the contrary, as are of a rounder figure slide smoothly along the papillæ, and are perceived to be sweet." In this manner they have with minute labour gone through the variety of imagined forms in bodies, and have given them as imaginary effects. All we can precisely determine on the nature of tastes is, that the bodies to be tasted must be either somewhat moistened or in some measure dissolved by the saliva, before they can produce a proper sensation; when both the tongue itself and the body to be tasted are extremely dry no taste whatever ensues. The sensation is then changed; and the tongue, instead of tasting, can only be said, like any other part of the body, to feel the object.

It is for this reason that children have a stronger relish of tastes than those who are more advanced in life. This organ with them, from the greater moisture of their bodies, is kept in greater perfection, and is consequently better adapted to perform its functions. Every person remembers how great a pleasure he found in sweets while a child; but his taste growing more obtuse with age, he is obliged to use artificial means to excite it. It is then that he is found to call in the assistance of powerful senses, and strong relishes of salts and aromatics—all which the delicacy of his tender organ in childhood was unable to endure. His taste grows callous to the natural relishes, and is artificially formed to others more unnatural; so that the highest epicure may be said to have the most depraved taste—as it is owing to the bluntness of his organs that he is obliged to have recourse to such a variety of expedients to gratify his appetite.

As smells are often rendered agreeable by habit, so also tastes may be. Tobacco and coffee, so pleasing to many, are yet at first very disagreeable to all. It is not without perseverance that we begin to have a relish for them; we force Nature so long, that what was constraint in the beginning at last becomes inclination.

The grossest and yet the most useful of all the senses is that of feeling. We are often seen to survive under the loss of the rest; but of this we can never be totally deprived excepting with life. Although this sense is diffused over all parts of the body, yet it most frequently happens that those parts which are most exercised in touching acquire the greatest degree of accuracy. Thus the fingers by long habit become greater masters in the art than any others, even where the sensation is more delicate and fine. It is from this habit, therefore, and their peculiar formation—and not, as is supposed, from their being furnished with a greater number of nerves—that the fingers are thus perfectly qualified to judge of forms. Blind men, who are obliged to use them much oftener, have this sense much finer; so that the delicacy of the touch arises rather from the habit of constantly employing the fingers than from any fancied nervousness in their conformation.

All animals that are furnished with hands seem to have more understanding than others. Monkeys have so many actions like those of men, that they appear to have similar ideas of the form of bodies. All other creatures deprived of hands can have no distinct ideas

of the shape of the objects by which they are surrounded, as they want this organ, which serves to examine and measure their forms, their risings, and their depressions. A quadruped, probably, conceives as erroneous an idea of anything near him as a child would of a rock or of a mountain that it beheld at a distance. It may be for this reason that we often see them frightened at things with which they ought to be better acquainted. Fishes, whose bodies are covered with scales, and who have no organs of feeling, must be the most stupid of all animals. Serpents, which are likewise destitute, are yet, by winding round several bodies, more capable of judging of their form. All these, however, can have but very imperfect ideas from feeling; and we have already seen, when deprived of this sense, how little the rest of the senses are to be relied on.

Feeling, therefore, is the guardian, the judge, and the examiner of all the rest of the senses. It establishes their information and detects their errors. All the other senses are altered by time, and contradict their former evidence; but the touch still continues the same; and, though extremely confined in its operations, yet it is never found to deceive. The universe, to a man who had only aided the rest of his senses, would be but a scene of illusion—every object misrepresented, and all its properties unknown. Mr. Buffon has imagined a man just newly brought into existence describing the illusion of his first sensations, and pointing out the steps by which he arrived at reality. He considers him as just created, and awaking amidst the productions of Nature; and, to animate the narrative still more strongly, he has made his philosophical man a speaker. The reader will no doubt recollect Adam's speech in Milton as being similar. All that I can say to obviate the imputation of plagiarism is, that the one treats the subject more as a poet, the other more as a philosopher. The philosopher's man describes his first sensations in the following manner:—

I well remember that joyful, anxious moment when I first became acquainted with my own existence. I was quite ignorant of what I was, how I was produced, or from whence I came. I opened my eyes: what an addition to my surprise! The light of the day, the azure vault of heaven, the verdure of the earth, the crystal of the waters—all employed me at once, and animated and filled me with inexpressible delight. I at first imagined that all these objects were within me, and made a part of myself.

Impressed with this idea I turned my eyes to the sun; its splendour dazzled and overpowered me; I shut them once more, and, to my great concern, I supposed that during this short interval of darkness I was again returning to nothing.

Afflicted, seized with astonishment, I pondered a moment on this great change, when I heard a variety of unexpected sounds. The whistling of the wind and the melody of the grove formed a concert, the softer cadence of which sunk upon my soul. I listened for some time, and was persuaded that all this music was within me.

Quite occupied with this new kind of existence, I had already forgotten the light which was my first inlet into life; when I once more opened my eyes, and found myself again in possession of my former happiness, the gratification of the two senses at once was a pleasure too great for utterance.

I turned my eyes upon a thousand various objects; I soon found that I could lose them and restore them at will; and amused myself more at leisure with a repetition of this new-made power.

I now began to gaze without emotion, and to hearken with tranquillity, when a light breeze, the freshness of which charmed me, wafted its perfumes to my sense of smelling, and gave me such satisfaction as even increased my self-love.

Agitated, roused by the various pleasures of my new

existence, I instantly arose, and perceived myself moved along as if by some unknown and secret power.

I had scarce proceeded forward when the novelty of my situation once more rendered me immovable. My surprise returned; I supposed that every object around me had been in motion; I gave to them that agitation which I produced by changing place; and the whole creation seemed once more in disorder.

I lifted my hand to my head; I touched my forehead; I felt my whole frame; I then supposed that my hand was the principal of my existence; all its formations were distinct and perfect, and so superior to the senses I had yet experienced, that I employed myself for some time in repeating its enjoyments: every part of my person I touched seemed to touch my hand in turn, and gave back sensation for sensation.

I soon found that this faculty was expanded over the whole surface of my body; and I now first began to perceive the limits of my existence, which I had in the beginning supposed spread over all the objects I saw.

Upon casting my eyes upon my body, and surveying my own form, I thought it greater than all the objects that surrounded me. I gazed upon my person with pleasure; I examined the formation of my hand and all its motions; it seemed to me large or little in proportion as I approached it to my eyes: I brought it very near, and it then hid almost every other object from my sight. I began soon, however, to find that my sight gave me uncertain information, and resolved to depend upon my feeling for redress.

This precaution was of the utmost service; I renewed my motions, and walked forward with my face turned towards the heavens. I happened to strike lightly against a palm-tree, and this renewed my surprise: I laid my hand on this strange body; it seemed replete with new wonders, for it did not return me sensation for sensation, as my former feelings had done. I perceived that there was something external, and which did not make a part of my own existence.

I now, therefore, resolved to touch whatever I saw, and vainly attempted to touch the sun; I stretched forth my arm, and felt only yielding air; at every effort I fell from one surprise into another, for every object appeared equally near me; and it was not till after an infinity of trials that I found some objects farther removed than the rest.

Amazed with the illusions and the uncertainty of my state, I sat down beneath a tree; and the most beautiful fruits hung upon it within my reach; I stretched forth my hand, and they instantly separated from the branch. I was proud of being able to grasp a substance without me; I held them up, and their weight appeared to me like an animated power that endeavoured to draw them to the earth. I found a pleasure in conquering their resistance.

I held them near my eye; I considered their form and beauty; their fragrance still more allured me to bring them nearer; I approached them to my lips, and drank in their odours; the perfume invited my sense of tasting, and I soon tried a new sense—how new! how exquisite! Hitherto I had tasted only of pleasure; but now it was luxury. The power of tasting gave me the idea of possession.

Flattered with this new acquisition, I continued its exercise, till, an agreeable languor stealing upon my mind, I felt all my limbs become heavy, and all my desires suspended. My sensations were now no longer vivid and distinct, but seemed to lose every object, and presented only feeble images confusedly marked. At that instant I sunk upon the flowery bank, and slumber seized me. All now seemed once more lost to me. It was then as if I was returning into my former nothing. How long my sleep continued I cannot tell, as I yet had no perception of time. My awaking appeared like a second birth; and I then perceived that I had ceased

for a time to exist. This produced a new sensation of fear, and from this interruption in life I began to conclude that I was not formed to exist for ever.

In this state of doubt and perplexity I began to harbour new suspicions, and to fear that sleep had robbed me of some of my late powers; when, turning on one side to resolve my doubts, what was my amazement to behold another being like myself stretched by my side! New ideas now began to arise; new passions, as yet unperceived, with fears and pleasures, all took possession of my mind and prompted my curiosity: love served to complete that happiness which was begun in the individual, and every sense was gratified in all its varieties.

## CHAP. X.

### OF OLD AGE, AND DEATH.

Everything in Nature has its improvement and its decay. The human form is no sooner arrived at its state of perfection than it begins to decline. The alteration is at first insensible; and often several years elapse before we find ourselves grown old. The news of this disagreeable change too generally comes from without; and we learn from others that we grow old before we are willing to believe the report.

When the body has come to its full height, and is extended into its just dimensions, it then also begins to receive an additional bulk, which rather loads than assists it. This is formed from fat, which generally, at the age of thirty-five or forty, covers all the muscles and interrupts their activity. Every action is then performed with greater labour, and the increase of size only serves as a forerunner of decay.

The bones, also, become every day more solid. In the embryo they are as soft almost as the muscles and the flesh; but by degrees they harden, and acquire their natural vigour; but still, however, the circulation is carried on through them, and how hard soever the bones may seem, yet the blood holds its current through them as through all other parts of the body. Of this we may be convinced by an experiment which was accidentally discovered by our ingenious countryman, Mr. Belcher. Perceiving at a friend's house that the bones of hogs which were fed upon madder were red, he tried it upon various animals by mixing this root with their usual food, and found that it tintured the bones in all—an evident demonstration that the juices of the body had a circulation through the bones. He fed some animals alternately upon madder and their common food for some time, and he found their bones tintured with alternate layers in conformity with their manner of living. From all this he naturally concluded that the blood circulated through the bones as it does through every other part of the body; and that, how solid soever they seemed, yet, like the softest parts, they were furnished through all their substances with their proper canals. Nevertheless, these canals are of very different capacities during the different stages of life. In infancy they are capacious, and the blood flows almost as freely through the bones as through any other part of the body. In manhood their size is greatly diminished; the vessels are almost imperceptible, and the circulation through them is proportionably slow. But in the decline of life, the blood which flows through the bones no longer contributing to their growth must necessarily serve to increase their hardness. The channels that everywhere run through the human frame may be compared to those pipes that we everywhere see crusted on the inside, by the water for a long continuance running through them. Both every day grow less and less, by the small rigid particles which are deposited within them. Thus as the vessels are by degrees diminished, the juices, also, which

were necessary for the circulation through them, are diminished in proportion; till at length, in old age, these props of the human frame are not only more solid but more brittle.

The cartilages or gristles, which may be considered as bones beginning to be formed, grow also more rigid. The juices circulating through them (for there is a circulation through all parts of the body) every day contribute to render them harder; so that these substances, which in youth are elastic and pliant in age, become pliant and bony. As these cartilages are generally placed near the joints, the motion of the joints also must of consequence become more difficult. Thus, in old age every action of the body is performed with labour; and the cartilages, formerly so supple, will now sooner break than bend.

As the cartilages acquire hardness and unfit the joints for motion, so also that mucous liquor which is always separated between the joints, and which serves, like oil to a hinge, to give them an easy and ready play, is now grown more scanty. It becomes thicker and more clammy—more unfit for answering the purposes of motion; and from thence, in old age every joint is not only stiff but awkward. At every motion this clammy liquor is heard to crack; and it is not without the greatest effort of the muscles that its resistance is overcome. I have seen an old person who never moved a single joint that did not thus give notice of the violence done it.

The membranes which cover the bones, the joints, and the rest of the body, become as we grow old more dense and more dry. Those which surround the bones soon cease to be ductile. The fibres, of which the muscles or flesh is composed, become every day more rigid; and, while to the touch the body seems as we advance in years to grow softer, it is in reality increasing in hardness. It is the skin and not the flesh that we feel upon such occasions. The fat and flabbiness of that seems to give an appearance of softness, which the flesh itself is very far from having. There are few can doubt this, after trying the difference between the flesh of young and old animals. The first is soft and tender—the last is hard and dry.

The skin is the only part of the body that age does not contribute to harden. That stretches to every degree of tension; and we have horrid instances of its pliancy in many disorders incident to humanity. In youth, therefore, while the body is vigorous and increasing, it still gives way to its growth. But although it thus adapts itself to our increase, it does not in the same manner conform to our decay. The skin, which in youth was filled and glossy, when the body begins to decline has not elasticity enough to shrink entirely with its diminution. It therefore hangs in wrinkles, which no art can remove. The wrinkles of the body in general proceed from this cause; but those of the face seem to proceed from another—namely, from the many varieties of positions into which it is put by the speech, the food, or the passions. Every grimace and every passion wrinkles up the visage into different forms. These are visible enough in young persons; but what at first was accidental or transitory becomes unalterably fixed in the visage as it grows older. From hence we may conclude that a freedom from passions not only adds to the happiness of the mind, but preserves the beauty of the face; and the person who has not felt their influence is less strongly marked by the decays of nature.

Hence, therefore, as we advance in age the bones, the cartilages, the membranes, the skin, and every fibre of the body become more solid, more brittle, and more dry. Every part shrinks—every motion becomes more slow; the circulation of the fluids is performed with less freedom—perspiration diminishes—the secretions alter—the digestion becomes slow and laborious—and the juices no longer serving to convey their accustomed nourishment, those parts may be said to live no longer

when the circulation ceases. Thus the body dies by little and little—all its functions are diminished by degrees—life is driven from one part of the frame to another—universal rigidity prevails—and death at last seizes upon the little that is left.

As the bones, the cartilages, the muscles, and all other parts of the body are softer in women than in men, these parts must consequently require a longer time to come to that hardness which hastens death. Women, therefore, ought to be a longer time in growing old than men; and this is actually the case. If we consult the tables which have been drawn up respecting human life, we shall find that, after a certain age, they are more long-lived than men, all other circumstances the same. A woman of sixty has a better chance than a man of the same age to live till eighty. Upon the whole, we may infer that such persons as have been slow in coming up to maturity will also be slow in growing old; and this holds as well with regard to other animals as to man.

The whole duration of the life of either vegetables or animals may be in some measure determined from their manner of coming to maturity. The tree or the animal which takes but a short time to increase to its utmost pitch perishes much sooner than such as are less premature. In both, the increase upwards is first accomplished; and not till they have acquired their greatest degree of height do they begin to spread in bulk. Man grows in stature till about the age of seventeen; but his body is not completely developed till about thirty. Dogs, on the other hand, are at their utmost size in a year, and in another year become as bulky as they usually are. However, man, who is so long in growing, continues to live for fourscore or a hundred years, but the dog seldom above twelve or thirteen. In general, also, it may be said that large animals live longer than little ones, as they usually take a longer time to grow; but in all animals one thing is equally certain—that they carry the causes of their own decay about with them, and that their deaths are necessary and inevitable. The prospects which some visionaries have formed of perpetuating life by remedies have been often enough proved false by their own example. Such unaccountable schemes would therefore have died with them, had not the love of life always augmented our credulity.

When the body is naturally well formed, it is possible to lengthen out the period of life for some years by management. Temperance in diet is often found conducive to this end. The famous Cornaro, who lived to above a hundred years, although his constitution was naturally feeble, is a strong instance of the benefit of an abstemious life. Moderation in the passions may also contribute to extend the term of our existence. Fontenelle, the celebrated French writer, was naturally of a very weak and delicate state of body. He was affected by the smallest irregularities, and frequently suffered severe fits of illness from the most trifling causes. But the remarkable equality of his temper and his seeming want of passion lengthened his life to more than a hundred years. It was remarkable for him that nothing could vex or make him uneasy; every occurrence seemed equally pleasing; and no event, however unfortunate, seemed to come unexpected. However, the term of life can be prolonged but for a little time by any art we can use. We are told of men who have lived beyond the ordinary duration of human existence—such as Parr, who lived to a hundred and forty-four; and Jenkins, who lived to a hundred and sixty-five. Yet these men used no peculiar arts to prolong life; on the contrary, it appears that these, as well as some others remarkable for their longevity, were peasants accustomed to the greatest fatigues—who had no settled rules of diet, but who often indulged in accidental excesses. Indeed, if we consider that the European, the Negro, the Chinese, and the American—the civilised man and the savage, the rich and the poor, the inhabitant of the city and of the country—though all so

different in other respects, are yet entirely similar in the period allotted to them for living; if we consider that neither the difference of race, of climate, of nourishment, of convenience, or of soil, makes any difference in the term of life—if we consider that those men who live upon raw flesh or dried fish, upon sago or rice, upon cassava or upon roots, nevertheless live as long as those who are fed upon bread and meat, we shall readily be brought to acknowledge that the duration of life depends neither upon habit, custom, nor the quality of food; we shall confess that nothing can change the laws of that mechanism which regulates the number of our years, and which can chiefly be affected only by long fasting or great excess.

If there be any difference in the different periods of man's existence, it ought principally to be ascribed to the quality of the air. It has been observed that in elevated situations there have been found more old people than in those that were low. The mountains of Scotland, Wales, Auvergne, and Switzerland have furnished more instances of extreme old age than the plains of Holland, Flanders, Germany, and Poland. But in general the duration of life is nearly the same in most countries. Man, if not cut off by accidental diseases, is often found to live to ninety or a hundred years. Our ancestors did not live beyond that date; and since the time of David this term has undergone very little alteration.

If we be asked how in the beginning men lived so much longer than at present, and by what means their lives were extended to nine hundred and thirty, or even nine hundred and sixty years, it may be answered, that the productions of the earth upon which they fed might be of a different nature at that time from what they are at present. It may be answered, that the term was abridged by Divine Command in order to keep the earth from being overstocked with human inhabitants; since, if every person were now to live and generate for nine hundred years, mankind would be increased to such a degree that there would be no room for subsistence; so that the plan of Providence would be altered—which is seen not to produce life without providing a proper supply.

But to whatever extent life may be prolonged, or however some may have delayed the effects of age, death is the certain goal to which all are hastening. All the causes of decay which have been mentioned contribute to bring on this dreadful dissolution. However, Nature approaches to this awful period by slow and imperceptible degrees; life is consuming day after day, and some one of our faculties or vital principles is every hour dying before the rest; so that death is only the last shade in the picture; and it is probable that man suffers a greater change in going from youth to age than from age into the grave. When we first begin to live, our lives may scarcely be said to be our own; as the child grows life increases in the same proportion, and is at its height in the prime of manhood. But as soon as the body begins to decrease life decreases also; for, as the human frame diminishes and its juices circulate in smaller quantities, life diminishes and circulates with less vigour; so that as we begin to live by degrees we begin to die in the same manner.

Why, then, should we fear death, if our lives have been such as not to make eternity dreadful? Why should we fear that moment which is prepared by a thousand other moments of the same kind?—the first pangs of sickness being probably greater than the last struggles of departure. Death in most persons is as calmly endured as the disorder that brings it on. If we inquire from those whose business it is to attend the sick and the dying, we shall find that, except in a very few acute cases where the patient dies in agonies, the greatest number die quietly, and seemingly without pain: and even the agonies of the former rather terrify the spectators than torment the patient; for how many have we who have

been accidentally relieved from this extremity, and yet had no memory of what they then endured? In fact, they had ceased to live during that time when they ceased to have sensation; and their pains were only those of which they had an idea.

The greatest number of mankind die, therefore, without sensation; and of those few that still preserve their faculties entire to the last moment, there is scarce one of them that does not also preserve the hopes of still outliving his disorder. Nature, for the happiness of man, has rendered this sentiment stronger than his reason. A person dying of an incurable disorder—which he must know to be so by the frequent examples of his case, which he perceives to be so by the inquietude of all around him, by the tears of his friends, and the departure of the face of the physician—is, nevertheless, still in hopes of getting over it. His interest is so great that he only attends to his own representations; the judgment of others is considered as a hasty conclusion: and while death every moment makes inroads upon his constitution, and destroys life in some part, hope still seems to escape the universal ruin, and is the last that submits to the blow.

Cast your eyes upon a sick man, who has a hundred times told you that he felt himself dying, that he was convinced he could not recover, and that he was ready to expire; examine what passes on his visage, when, through zeal or indiscretion, any one comes to tell him that his end is at hand. You will see him change, like one who is told an unexpected piece of news. He now appears not to have thoroughly believed what he had been telling you himself; he doubted much, and his fears were greater than his hopes: but he still had some feeble expectations of living, and would not have seen the approaches of death unless he had been alarmed by the mistaken assiduity of his attendants.

Death, therefore, is not that terrible thing which we suppose it to be. It is a spectre which frightens us at a distance, but which disappears when we come to approach it more closely. Our ideas of its terrors are conceived in prejudice, and dressed up by fancy; we regard it not only as the greatest misfortune, but as also an evil accompanied with the most excruciating tortures; we have even increased our apprehensions by reasoning on the extent of our sufferings. "It must be dreadful," say some, "since it is sufficient to separate the soul from the body; it must be long, since our sufferings are proportioned to the succession of our ideas; and these, being painful, must succeed each other with extreme rapidity." In this manner has false philosophy laboured to augment the miseries of our nature, and to aggravate that period which Nature has kindly covered with insensibility. Neither the mind nor the body can suffer these calamities; the mind is at that time mostly without ideas, and the body too much enfeebled to be capable of perceiving its pain. A very acute pain produces either death or fainting, which is a state similar to death. The body can suffer but to a certain degree; if the torture becomes excessive it destroys itself, and the mind ceases to perceive when the body can no longer endure.

In this manner excessive pain admits of no reflection; and wherever there are any signs of it, we may be sure that the sufferings of the patient are no greater than what we ourselves may remember to have endured.

But, in the article of death, we have many instances in which the dying person has shown that very reflection which presupposes an absence of the greatest pain; and consequently that pang which ends life cannot even be so great as those which have preceded. Thus, when Charles XII. was shot at the siege of Frederickshall, he was seen to clap his hand on the hilt of his sword; and although the blow was great enough to terminate one of the boldest and bravest lives in the world, yet it was not painful enough to destroy reflection. He perceived himself attacked; he reflected that he ought to defend

himself—and his body obeyed the impulse of his mind, even in the last extremity. Thus it is the prejudice of persons in health, and not the body in pain, that makes us suffer from the approach of death: we have all our lives contracted a habit of making out excessive pleasures and pains; and nothing but repeated experience shows us how seldom the one can be suffered or the other enjoyed to the utmost.

If there be anything necessary to confirm what we have said concerning the gradual cessation of life or the insensible approaches of our end, nothing can more effectually prove it than the uncertainty of the signs of death. If we consult what Winslow or Bruhier have said upon this subject, we shall be convinced that between life and death the shade is so very undistinguishable, that even all the powers of art can scarcely determine where the one ends and the other begins. The colour of the visage, the warmth of the body, the suppleness of the joints, are but uncertain signs of life still subsisting; while, on the contrary, the paleness of the complexion, the coldness of the body, the stiffness of the extremities, the cessation of all motion, and the total insensibility of all the parts, are but uncertain marks of death begun. In the same manner, also, with regard to the pulse and the breathing, these motions are often kept under that it is impossible to perceive them. By approaching a looking-glass to the mouth of a person supposed to be dead, people often expect to find whether he breathes or not. But this is a very uncertain experiment: the glass is frequently sullied by the vapour of the dead man's body; and often the person is still alive although the glass is no way tarnished. In the same manner neither burning nor scarifying, neither noises in the ears nor pungent spirits applied to the nostrils, give certain signs of the discontinuance of life; and there are many instances of persons who have endured them all, and afterwards recovered without any external assistance, to the astonishment of the spectators. How careful, therefore, should we be, before we commit those who are dearest to us to the grave, to be well assured of their departure: experience, justice, humanity, all persuade us not to hasten the funerals of our friends, but to keep their bodies unburied until we have certain signs of their real decease.

## CHAP. XI.

### OF THE VARIETIES IN THE HUMAN RACE.

Hitherto we have compared man with other animals; we now come to compare men with each other. We have hitherto considered him as an individual endowed with excellencies above the rest of the creation; we now come to consider the advantages which men have over men, and the various kinds with which our earth is inhabited.

If we compare the minute differences of mankind, there is scarce one nation upon the earth that entirely resembles another; and there may be said to be as many different kinds of men as there are countries inhabited. One polished nation does not differ more from another than the merest savages do from those savages that lie even contiguous to them; and it frequently happens that a river or a mountain divides two barbarous tribes that are unlike each other in manners, customs, features, and complexion. But these differences, however perceivable, do not form such distinctions as come within a general picture of the varieties of mankind. Custom, accident, or fashion may produce considerable alterations in neighbouring nations. Their being derived from ancestors of a different climate or complexion may contribute to make accidental distinctions, which every day grow less; and it may be said that two neighbour-

ing nations, how unlike soever, at first, will assimilate by degrees—and, by long continuance, the difference between them will at last become almost imperceptible. It is not, therefore, between contiguous nations we are to look for any strong marked varieties in the human species; it is by comparing the inhabitants of opposite climates and distant countries—those who live within the polar circle with those who live beneath the equator—those who live on one side of the globe with those who occupy the other.

Of all animals, the differences between mankind are the smallest. Of the lower races of creatures the changes are so great as often entirely to disguise the natural animal, and to distort or disfigure its shape. But the chief differences in man are rather taken from the tincture of his skin than the variety of his figure; and in all climates he preserves his erect deportment and the marked superiority of his form. If we look round the world, there seem to be not above six distinct varieties in the human species, each of which is strongly marked, and speaks the kind seldom to have mixed with any other. But there is nothing in the shape, nothing in the faculties, that shows their different origins; and the varieties of climate, of nourishment, and custom are sufficient to produce every change.

The first distinct race of men is found round the polar regions. The Laplanders, the Esquimaux Indians, the Samoid Tartars, the inhabitants of Nova Zembla, the Boranians, the Greenlanders, and the natives of Kamtschatka, may be considered as one peculiar race of people—all greatly resembling each other in their stature, their complexion, their customs, and their ignorance. These nations being under a rigorous climate, where the productions of Nature are but few and the provisions coarse and unwholesome, their bodies have shrunk to the nature of their food; their complexions have suffered from cold almost a similar change to what heat is known to produce—their colour being a deep brown, in some places inclining to actual blackness. These, therefore, in general are found to be a race of short stature and odd shape, with countenances as savage as their manners are barbarous. The visage in these countries is large and broad, the nose flat and short, the eyes of a yellowish brown inclining to blackness, the eye-lids drawn towards the temples, the cheek-bones extremely high, the mouth very large, the lips thick and turned outwards, the voice thin and squeaking, the head large, the hair black and straight, the skin of a dark-greyish colour. They are short in stature, the generality not being above four feet high, and the tallest not above five. Among all these nations the women are deformed as the men, and they resemble them so nearly that one cannot at first distinguish the sexes among them.

These nations not only resemble each other in their deformity, their dwarfishness, and the colour of their hair and eyes, but they have in a great measure the same inclinations and the same manners, being all equally rude, superstitious, and stupid. The Danish Laplanders have a large black cat, to which they communicate their secrets and consult in all their affairs. Among the Swedish Laplanders there is in every family a drum for consulting the devil; and although these nations are robust and nimble, yet they are so cowardly that they never can be brought into the field. Gustavus Adolphus attempted to form a regiment of Laplanders, but he found it impossible to accomplish his design; for it would seem that they can live only in their own country and in their own manner. They make use of skates, which are made of fir, of near three feet long and half a foot broad; these are pointed, raised before, and tied to the foot by straps of leather. With these they skate upon the icy snow with such velocity, that they very easily overtake the swiftest animals. They make use also of a pole, pointed with iron at one end and rounded at the other. This pole serves to push them along, to direct their course,

to support them from falling, to stop the impetuosity of their motion, and to kill the game which they have overtaken. Upon these skates they descend the steepest mountains and scale the most craggy precipices; and in these exercises the women are not less skilful than the men. They have all the use of the bow and arrow, which seems to be a contrivance common to all barbarous nations; and which at first, however, required no small skill to invent. They launch a javelin, also, with great force; some say they can hit a mark no larger than a crown-piece at thirty yards distance, and with such force as would pierce a man through. They are all hunters, and particularly pursue the ermine, the fox, the ounce, and the martin, for the sake of their skins. These they barter with their southern neighbours for brandy and tobacco, both of which they are fond of to excess. Their food is principally dried fish, the flesh of rein-deer, and bears. Their bread is composed of the bones of fishes pounded and mixed with the inside tender bark of the pine-tree. Their drink is train-oil or brandy, and, when deprived of these, water in which juniper-berries have been infused. With regard to their morals, they have all the virtues of simplicity and all the vices of ignorance. They offer their wives and daughters to strangers, and seem to think it a particular honour if their offer is accepted. They have no idea of religion or a Supreme Being; the greatest number of them are idolators; and their superstition is as profound as their worship is contemptible. Wretched and ignorant as they are, yet they do not want pride; they set themselves far above the rest of mankind; and Krantz assures us, that when the Greenlanders are got together nothing is so customary among them as to turn the Europeans into ridicule. They are obliged, indeed, to yield them the pre-eminence in understanding and mechanical arts; but they do not know how to appreciate them. They therefore count themselves the only civilised and well-bred people in the world; and it is common with them, when they see a quiet or a modest stranger, to say that he is almost as well bred as a Greenlander.

From this description, therefore, this whole race of people may be considered as distinct from any other. Their long continuance in a climate the most inhospitable, their being obliged to subsist on food the most coarse and ill prepared, the savageness of their manners, and their laborious lives, all have contributed to shorten their stature and to deform their bodies. In proportion as we approach towards the north pole the size of the natives appear to diminish, growing less and less as we advance higher, till we come to those latitudes that are destitute of all inhabitants whatsoever.

The wretched natives of these climates seem fitted by Nature to endure the rigours of their situation. As their food is but scanty and precarious, their patience in hunger is amazing. A man who has eaten nothing for four days can manage his little canoe in the most furious waves, and calmly subsist in the midst of a tempest that would quickly dash a European boat to pieces. Their strength is not less amazing than their patience; a woman among them will carry a piece of timber or a stone near double the weight of what a European can lift. Their bodies are of a dark grey all over, and their faces brown or olive. The tincture of their skins partly seems to arise from their dirty manner of living, being generally daubed with train-oil; and partly from the rigours of climate, as the sudden alterations of cold and raw air in winter, and of burning heats in summer, shade their complexions by degrees, till, in a succession of generations, they at last become almost black. As the countries in which these reside are the most barren, so the natives seem the most barbarous of any part of the earth. Their more southern neighbours of America treat them with the same scorn that a polished nation would treat a savage one; and we may readily judge of the rudeness of those manners which

even a native of Canada can think more barbarous than his own.

But the gradations of Nature are imperceptible; and, while the north is peopled with such miserable inhabitants, there are here and there to be found upon the edges of these regions people of larger stature and completer figure. A whole race of the dwarfish breed is often found to come down from the north, and settle more to the southward; and, on the contrary, it sometimes happens that southern nations are seen higher up in the midst of these diminutive tribes, where they have continued for time immemorial. Thus the Ostiac Tartars seem to be a race that have travelled down from the north, and to be originally sprung from the minute savages we have been describing. There are also Norwegians and Finlanders of proper stature, who are seen to inhabit in latitudes higher even than Lapland. These, however, are but accidental migrations, and serve as shades to unite the distinct varieties of mankind.

The second great variety in the human species seems to be that of the Tartar race; from whence, probably, the little men we have been describing originally proceeded. The Tartar country, taken in general, comprehends the greatest part of Asia; and is consequently a general name given to a number of nations of various forms and complexions. But however they seem to differ from each other, they all agree in being very unlike the people of any other country. All the nations have the upper part of the visage very broad, and wrinkled even while yet in their youth. Their noses are short and flat, their eyes little, and sunk in their heads; and, in some of them, they are seen five or six inches asunder. Their cheek-bones are high, the lower part of their visage narrow, the chin long and advanced forward, their teeth of an enormous size, and growing separate from each other; their eye-brows thick, large, and covering their eyes; their eye-lids thick, the face broad and flat, the complexion olive-coloured, and the hair black. They are of a middle size, extremely strong, and very robust. They have but little beard, which grows stragglingly on the chin. They have large thighs and short legs. The ugliest of all are the Calmucks, in whose appearance there seems to be something frightful. They all lead an erratic life, remaining under tents of hair or skins. They live upon horse-flesh and that of camels, either raw or a little sodden between the horse and the saddle. They also eat fish dried in the sun. Their most usual drink is mares' milk fermented with millet ground into meal. They all have the head shaven, except a lock of hair on the top, which they let grow sufficiently long to form into tresses on each side of the face. The women, who are as ugly as the men, wear their hair, which they bind up with bits of copper and other ornaments of a like nature. The majority of these nations have no religion, no settled notions of morality, no decency of behaviour. They are chiefly robbers: and the natives of Dagestan, who live near their more polished neighbours, make a traffic of Tartar slaves who have been stolen, and sell them to the Turks and the Persians. Their chief riches consist in horses, of which perhaps there are more in Tartary than in any other part of the world. The natives are taught by custom to live in the same place with their horses; they are continually employed in managing them, and at last bring them to such great obedience that the horse seems actually to understand the rider's intention.

To this race of men we must also refer the Chinese and the Japanese, however different they seem in their manners and ceremonies. It is the form of the body that we are now principally considering; and there is between these countries a surprising resemblance. It is in general allowed that the Chinese have broad faces, small eyes, flat noses, and scarce any beard; that they are broad and square-shouldered, and rather less in stature than Europeans. These are marks common to

them and the Tartars, and they may therefore be considered as being derived from the original. "I have observed," says Chardin, "that in all the people from the east and the north of the Caspian Sea to the peninsula of Malacca that the lines of the face and the formation of the visage is the same. This has induced me to believe that all these nations are derived from the same original, however different either their complexions or their manners may appear; for as to the complexion, that proceeds entirely from the climate and the food; and as to the manners, these are generally the result of their different degrees of wealth or power." That they come from one stock is also evident from this—that the Tartars who settle in China soon resemble the Chinese; and, on the contrary, the Chinese who settle in Tartary soon assume the figure and the manners of the Tartars.

The Japanese so much resemble the Chinese, that one cannot hesitate to rank them in the same class. They only differ in being rather browner, as they inhabit a more southern climate. They are in general described as of a brown complexion, a short stature, a broad flat face, a very little beard, and black hair. Their customs and ceremonies are nearly the same, their ideas of beauty similar, and their artificial deformities of blackening the teeth and bandaging the feet entirely alike in both countries. They both, therefore, proceed from the same stock; and although they differ very much from their brutal progenitors, yet they owe their civilisation wholly to the mildness of the climate in which they reside, and to the soil's peculiar fertility. To this tribe we may also refer the Cochin Chinese, the Siamese, the Tonquinese, and the inhabitants of Aracan, Laos, and Pegu, who, though all differing from the Chinese and each other, nevertheless have too strong a resemblance not to betray their common origin.

Another, which makes the third variety in the human species, is that of the Southern Asiatics, the form of whose features and persons may be easily distinguished from those of the Tartar races. The nations that inhabit the peninsula of India seem to be the principal flock from whence the inhabitants of the islands which lie scattered over the Indian Ocean have been peopled. They are in general of a slender shape, with long, straight, black hair, and often with Roman noses. Thus they resemble the Europeans in stature and features, but greatly differ in colour and habit of body. The Indians are of an olive colour, and in the more southern parts quite black—although the word *Mogul* in their language signifies a white man. The women are extremely delicate, and bathe very often: they are of an olive colour as well as the men; their legs and thighs are long and their bodies short, which is the opposite to what is seen among the women of Europe. They are, as I am informed, by no means so fruitful as the European women; but they feel the pains of child-birth with much less sensibility, and are generally up and well the day following. In fact, these pains seem greatest in all countries where the women are the most delicate, or the constitution enfeebled by luxury or indolence. The women of savage nations seem in a great measure exempt from painful labours; and even the hard-working wives of the peasants among ourselves have this advantage from a life of industry, that their child-bearing is less painful. Over all India the children arrive sooner at maturity than with us in Europe. They often marry and consummate—the husband at ten years old and the wife at eight; and they frequently have children at that age. However, the women who are mothers so soon cease bearing before they are thirty; and at that time they appear wrinkled, and seem marked with all the deformities of age. The Indians have long been remarkable for their cowardice and effeminacy—every hero that has but attempted to invade their country having succeeded. The warmth of the climate entirely influences their manners; they are slothful, submissive, and luxu-

rious; satisfied with sensual happiness alone, they find no pleasure in thinking; and contented with slavery, they are ready to obey any master. Many tribes among them eat nothing that has life; they are fearful of killing the meanest insect; and have even erected hospitals for the maintenance of all kinds of vermin. The Asiatic dress is a loose flowing garment, rather fitted for the purposes of peace and indolence than of industry or war. The vigour of the Asiatics is in general conformable to their dress and nourishment: fed upon rice, and clothed in effeminate silk vestments, their soldiers are unable to oppose the onset of a European army; and from the time of Alexander to the present day we have scarce any instance of their success in arms. Upon the whole, therefore, they may be considered as a feeble race of sensualists, too dull to find rapture in any pleasures, and too indolent to turn their gravity into wisdom. To this class we may refer the Persians and Arabians, and, in general, the inhabitants of the islands that lie scattered in the Indian Ocean.

The fourth striking variety in the human species is to be found among the Negroes of Africa. This gloomy race of mankind is found to blacken all the southern parts of Africa, from eighteen degrees north of the line to its extreme termination at the Cape of Good Hope. I know it is said that the Caffres, who inhabit the southern extremity of that large continent, are not to be ranked among the Negro race; however, the difference between them in point of colour and features is so small, that they may very easily be grouped in this general picture; and in the one or two that I have seen I could not perceive the smallest difference. Each of the Negro nations, it must be owned, differ from each other; they have their peculiar countries for beauty, like us; and different nations, as in Europe, pride themselves upon the regularity of their features. Those of Guinea, for instance, are extremely ugly, and have an unsupportable scent; those of Mosambique are reckoned beautiful, and have no ill smell whatsoever. The Negroes in general are of a black colour, with a smooth soft skin. This smoothness proceeds from the downy softness of the hair which grows upon it, the strength of which gives a roughness to the feel in those of a white complexion. Their skins, therefore, have a velvet smoothness, and seem less braced upon the muscles than ours. The hair of their heads differs entirely from what we are accustomed to, being soft, woolly, and short. The beard, also, partakes of the same qualities; but in this it differs, that it soon turns grey, which the hair is seldom found to do; so that several are seen with white beards and black hair at the same time. Their eyes are generally of a deep hazle; their noses flat and short; their lips thick and tumid; and their teeth of an ivory whiteness. This their only beauty, however, is set off by the colour of their skin; the contrast between the black and white being the more observable. It is false to say that their features are deformed by art; since, in the Negro children born in European countries, the same deformities are seen to prevail—the same flatness in the nose and the same prominence in the lips. They are in general said to be well shaped; but of such as I have seen I never found one that might be justly called so—their legs being mostly ill formed, and commonly bending outward on the shin-bone. But it is not only in those parts of their bodies that are obvious that they are disproportioned; those parts which among us are usually concealed by dress with them are large and languid. The women's breasts after bearing one child hang down below the navel; and it is customary with them to suckle the child at their backs by throwing the breast over the shoulder. As their persons are thus naturally deformed, at least to our imaginations, their minds are equally incapable of strong exertions. The climate seems to relax their mental powers still more than those of the body; they are, therefore, in general found to be

stupid, indolent, and mischievous. The Arabians themselves, many colonies of whom have migrated southward into the most inland parts of Africa, seem to have degenerated from their ancestors; and forgetting their ancient learning and losing their beauty, they have become a race scarce any way distinguishable from the original natives. Nor does it seem to have fared otherwise with the Portuguese, who, about two centuries ago, settled along this coast. They also are become almost as black as the Negroes; and are said by some to be even more barbarous.

The inhabitants of America make a fifth race, as different from all the rest in colour as they are distinct in habitation. The natives of America (except in the northern extremity, where they resemble the Laplanders) are of a red or copper colour; and although, in the old world, different climates produce a variety of complexions and customs, the natives of the new continent seem to resemble each other in almost every respect. They are all nearly of one colour; all have black, thick, straight hair, and thin black beards, which, however, they take care to pluck out by the roots. They have in general flat noses, with high cheek-bones and small eyes, and these deformities of nature they endeavour to increase by art: they flatten the nose, and often the whole head, of their children, while the bones are yet susceptible of every impression. They paint the body and face of various colours, and consider the hair upon any part of it except the head as a deformity which they are careful to eradicate. Their limbs are generally slighter made than those of the Europeans; and I am assured they are far from being so strong. All these savages seem to be cowardly; they seldom are known to face their enemies in the field, but fall upon them at an advantage, and the greatness of their fears serves to increase the rigours of their cruelty. The wants which they often sustain make them surprisingly patient in adversity; distress, by being grown familiar, becomes less terrible; so that their patience is less the result of fortitude than of custom. They have all a serious air, although they seldom think; and, however cruel to their enemies, are kind and just to each other. In short, the customs of savage nations in every country are almost the same; a wild, independent, and precarious life produces a peculiar train of virtues and vices; and patience and hospitality, indolence and rapacity, content and sincerity, are found not less among the natives of America than all the barbarous nations of the globe.

The sixth and last variety of the human species is that of the Europeans, and the nations bordering on them. In this class we may mention the Georgians, Circassians, and Mingrelians—the inhabitants of Asia Minor and the northern parts of Africa—together with a part of those countries which lie north-west of the Caspian Sea. The inhabitants of these countries differ a good deal from each other; but they generally agree in the colour of their bodies, the beauty of their complexions, the largeness of their limbs, and the vigour of their understanding. Those arts which might have had their invention among other races of mankind have come to perfection there. In barbarous countries, the inhabitants go either naked or are awkwardly clothed in furs or feathers; in countries semi-barbarous the robes are loose and flowing; but here the clothing is less made for show than expedition, and unites as much as possible the extremes of ornament and despatch.

To one or other of these classes we may refer the people of every country; and as each nation has been less visited by strangers, or has had less commerce with the rest of mankind, we find their persons and their manners more strongly impressed with one or other of the characters mentioned above. On the contrary, in those places where trade has long flourished, or where enemies have made many incursions, the races are usually found blended, and properly fall beneath no one cha-

racter. Thus, in the islands of the Indian Ocean, where a trade has been carried on for time immemorial, the inhabitants appear to be a mixture of all the nations upon the earth; white, olive, brown, and black men are all seen living together in the same city, and propagate a mixed breed that can be referred to none of the classes into which naturalists have thought proper to divide mankind.

Of all the colours by which mankind is diversified, it is easy to perceive that ours is not only the most beautiful to the eye but the most advantageous. The fair complexion seems, if I may so express it, as a transparent covering to the soul; all the variations of the passions, every expression of joy or sorrow, flows to the cheek, and, without language, marks the mind. In the slightest change of health, also, the colour of the European face is the most exact index, and often teaches us to prevent those disorders that we do not as yet perceive: not but that the African black and the Asiatic olive complexions admit of their alterations also; but these are neither so distinct nor so visible as with us; and, in some countries, the colour of the visage is never found to change; but the face continues in the same settled shade in shame and in sickness, in anger and despair.

The colour, therefore, most natural to man ought to be that which is most becoming; and it is found that in all regions the children are born fair, or at least red, and that they grow more black or tawny as they advance in age. It would seem, therefore, that man is naturally white; since the same causes that darken the complexion in infants may have originally operated in slower degrees in blackening whole nations. We could therefore readily account for the blackness of different nations, did we not see the Americans, who live under the line, as well as the natives of Negroland, who are of a red colour, and but a very small shade darker than the natives of the northern latitudes in the same continent. For this reason, some have sought for other causes of blackness than the climate; and have endeavoured to prove that the blacks are a race of people bred from one man, who was marked with accidental blackness. This, however, is but mere ungrounded conjecture; and, although the Americans are not so dark as the Negroes, yet we must still continue in the ancient opinion that the deepness of the colour proceeds from the excessive heat of the climate; for if we compare the heats of Africa with those of America, we shall find they bear no proportion to each other. In America, all that part of the continent which lies under the line is cool and pleasant, either shaded by mountains or refreshed by breezes from the sea; but in Africa, the wide tract of country that lies under the line is very extensive, and the soil sandy; the reflection of the sun, therefore, from so large a surface of earth is almost intolerable; and it is not to be wondered at that the inhabitants should bear in their looks marks of the inhospitable climate. In America the country is but thinly inhabited, and the more torrid tracts are generally left desert by the inhabitants, for which reason they are not so deeply tinged by the beams of the sun; but in Africa the whole face of the country is fully peopled, and the natives are obliged to endure their situation without the power of migration. It is there, consequently, that they are in a manner tied down to feel all the severity of the heat; and their complexions take the darkest hue they are capable of receiving. We need not, therefore, have recourse to any imaginary propagation from persons accidentally black, since the climate is an obvious and sufficient cause to produce the effect.

In fact, if we examine the complexions of different countries we shall find them darken in proportion to the heat of their climate, and the shades gradually to deepen as they approach the line. Some nations, indeed, may be found not so much tinged by the sun as others, although they lie nearer the line; but this ever proceeds

from some accidental causes—either from the country lying higher, and consequently being colder, or from the natives bathing oftener, and leading a more civilised life. In general, it may be asserted that as we approach the line we find the inhabitants of each country grow browner, until the colour deepens into perfect blackness. Thus, taking our standard from the whitest race of people, and beginning with our own country—which, I believe, bids fairest for pre-eminence—we shall find the French, who are more southern, a slight shade deeper than we; going farther down, the Spaniards are browner than the French; the inhabitants of Fez darker than they; and the natives of Negroland the darkest of all. In what manner the sun produces this effect, and how the same luminary which whitens wax and linen should darken the human complexion, is not easy to conceive. Sir Thomas Brown first supposed that a mucous substance, which had something of a vitriolic quality, settled under the reticular membrane, and grew darker with heat. Others have supposed that the blackness lay in the epidermis, or scarf-skin, which was burned up like leather. But nothing has been satisfactorily discovered upon the subject; it is sufficient that we are assured of the fact, and that we have no doubt of the sun's tinging the complexion in proportion to its vicinity.

But we are not to suppose that the sun is the only cause of darkening the skin; the wind, extreme cold, hard labour, or coarse and sparing nourishment, are found to contribute to this effect. We find the peasants of every country, who are most exposed to the weather, a shade darker than the higher ranks of people. The savage inhabitants of all places are exposed still more, and therefore contract a still deeper hue; and this will account for the tawny colour of the North American Indians. Although they live in a climate the same, or even more northerly than ours, yet they are found to be of complexions very different from those of Europe. But it must be considered that they live continually exposed to the sun; that they use many methods to darken their skins by art, painting them with red ochre, and anointing them with the fat of bears. Had they taken, for a succession of several generations, the same precautions to brighten their colour that an European does, it is very probable that they would in time come to have similar complexions, and, perhaps, dispute the prize of beauty.

The extremity of cold is not less productive of a tawny complexion than that of heat. The natives of the arctic circle, as was observed, are all brown; and those that lie most to the north are almost entirely black. In this manner both extremes are unfavourable to the human form and colour, and the same effects are produced under the poles that are found at the line.

With regard to the stature of the different countries, that seems chiefly to result from the nature of the food and the quantity of the supply. Not but that the severity of heat or cold may in some measure diminish the growth and produce a dwarfishness of make; but in general the food is the great agent in producing this effect; where that is supplied in large quantities, and where its quality is wholesome and nutrimental, the inhabitants are generally seen above the ordinary stature. On the contrary, where it is afforded in a sparing quantity, or very coarse and void of nourishment in its kind, the inhabitants degenerate, and sink below the ordinary size of mankind. In this respect they resemble other animals whose bodies, by proper feeding, may be greatly augmented. An ox on the fertile plains of India grows to a size four times as large as the diminutive animal of the same kind bred in the Alps. The horses bred in the plains are larger than those of the mountain. So it is with man; the inhabitants of the valley are usually found taller than those of the hill: the natives of the Highlands of Scotland, for instance, are short, broad, and hardy; those of the Lowlands are tall and shapely.

The inhabitants of Greenland, who live upon dried fish and seals, are less than those of Gambia or Senegal, where Nature supplies them with vegetable and animal abundance.

The form of the face seems rather to be the result of custom. Nations who have long considered some artificial deformity as beautiful, who have industriously lessened the feet or flattened the nose, by degrees begin to receive the impression they are taught to assume; and Nature, in a course of ages, shapes itself to the constraint and assumes hereditary deformity. We find nothing more common in births than for children to inherit sometimes even the accidental deformities of their parents. We have many instances of squinting in the father, which he received from fright or habit, communicated to the offspring; and I myself have seen a child distinctly marked with a scar similar to one the father had received in battle. In this manner accidental deformities may become natural ones, and by assiduity may be continued, and even increased, through successive generations. From this, therefore, have arisen the small eyes and long ears of the Tartars and Chinese nations. From hence originally may have come the flat noses of the blacks, and the flat heads of the American Indians.

In this slight survey, therefore, I think we may see that all the variations in the human figure, as far as they differ from our own, are produced either by the rigour of the climate, the bad quality or the scantiness of the provisions, or by the savage customs of the country. They are actual marks of the degeneracy in the human form; and we may consider the European figure and colour as standards to which to refer all other varieties, and with which to compare them. In proportion as the Tartar or American approaches nearer to European beauty, we consider the race as less degenerated; in proportion as he differs more widely, he has made greater deviations from his original form.

That we have all sprung from one common parent we are taught, both by reason and religion, to believe; and we have good reason also to think that the Europeans resemble him more than any of the rest of his children. However, it must not be concealed that the olive-coloured Asiatic, and even the jet-black Negro, claim this honour of hereditary resemblance; and assert that white men are mere deviations from original perfection. Odd as this opinion may seem, they have Linnæus, the celebrated naturalist, on their side, who supposes man to be a native of the tropical climates, and only a sojourner more to the north. But, not to enter into a controversy upon a matter of a very remote speculation, I think one argument alone will suffice to prove the contrary, and show that the white man is the original source from whence the other varieties have sprung. We have frequently seen white children produced from black parents, but have never seen a black offspring the production of two whites. From hence we may conclude, that whiteness is the colour to which mankind naturally tends; for, as in the tulip, the parent stock is known by all the artificial varieties breaking into it, so in man that colour must be original which never alters, and to which all the rest are accidentally seen to change. I have seen in London at different times two white Negroes, the issue of black parents, that served to convince me of the truth of this theory. I had before been taught to believe that the whiteness of the Negro skin was a disease—a kind of milky whiteness, that might be called rather a leperous crust than a natural complexion. I was taught to suppose that the numberless white Negroes found in various parts of Africa, the white men that go by the name of Chacrelas in the East Indies, and the white Americans near the Isthmus of Darien, in the West Indies, were all so many diseased persons, and even more deformed than the blackest of the natives. But examining the Negro who was last shown in London, I found the colour to be exactly like that of an

European—the visage white and ruddy, and the lips of the proper redness. However, there were sufficient marks to convince me of its descent. The hair was white and woolly, and very unlike anything I had seen before. The iris of the eye was yellow, inclining to red; the nose was flat, exactly resembling that of a Negro; and the lips thick and prominent. No doubt, therefore, remained of the child's having been born of Negro parents: and the person who showed it had attestations to convince the most incredulous. From this, then, we see that the variations of the Negro colour is into whiteness, whereas the white are never found to have a race of Negro children. Upon the whole, therefore, all those changes which the African, the Asiatic, or the American undergo are but accidental deformities, which a kinder climate, better nourishment, or more civilized manners, would in a course of centuries very probably remove.

## CHAP. XII.

### OF MONSTERS.

Hitherto I have only spoken of those varieties in the human species that are common to whole nations; but there are varieties of another kind which are only found in the individual, and being more rarely seen, are therefore called "monstrous." If we examine into the varieties of distorted Nature, there is scarce a limb of the body or a feature in the face that has not suffered some reprobation, either from Art or Nature—being enlarged or diminished, lengthened or wrested, from its due proportion. Linnæus, after having giving a catalogue of monsters, particularly adds the flat heads of Canada, the long heads of the Chinese, and the slender waists of the women of Europe, who, by tight lacing, take such pains to destroy the health through a mistaken desire to improve their beauty. It belongs more to the physician than the naturalist to attend to these minute deformities; and, indeed, it is a melancholy contemplation to speculate upon a catalogue of calamities inflicted by unpitying Nature, or brought upon us by our own caprice. Some, however, are fond of such accounts; and there have been books filled with nothing else. To these, therefore, I refer the reader; who may be better pleased with accounts of men with two heads, or without any head, of children joined in the middle, of bones turned into flesh, or flesh converted into bones, than I am. It is sufficient here to observe, that every day's experience must have shown us miserable instances of this kind produced by Nature or Affection—calamities that no pity can soften or assiduity relieve.

Passing over, therefore, every other account, I shall only mention the extraordinary instance quoted by Malbranche, upon which he founds his beautiful theory of monstrous productions. A woman of Paris, the wife of a tradesman, went to see a criminal broke alive upon the wheel at the place of public execution. She was at that time two months advanced in pregnancy, and no way subject to any disorders to affect the child in her womb. She was, however, of a tender habit of body; and, though led by curiosity to this horrid spectacle, very easily moved to pity and compassion. She felt, therefore, all those strong emotions which so terrible a sight must naturally inspire; shuddered at every blow the criminal received, and almost swooned at his cries. Upon returning from this scene of blood she continued for some days pensive, and her imagination still wrought upon the spectacle she had lately seen. After some time, however, she seemed perfectly recovered from her fright, and had almost forgotten her former uneasiness. When the time of her delivery approached she seemed no ways mindful of her former terrors, nor were her pains in labour more than usual in such circumstances.

But what was the amazement of her friends and assistants when the child came into the world! It was found that every limb in its body was broken like those of the malefactor, and just in the same place. This poor infant, that had suffered the pains of life even before its coming into the world, did not die, but lived in an hospital in Paris for twenty-one years after—a wretched instance of the supposed powers of imagination in the mother of altering and distorting the infant in the womb. The manner in which Malbranche reasons upon this fact is as follows:—The Creator has established such a sympathy between the several parts of Nature, that we are led not only to imitate each other, but also to partake in the same affections and desires. The animal spirits are thus carried to the respective parts of the body to perform the same actions which we see others perform, to receive in some measure their wounds, and take part in their sufferings. Experience tells us that if we look attentively on any person severely beaten or severely wounded, the spirits immediately flow into those parts of the body which correspond to those we see in pain. The more delicate the constitution the more it is thus affected—the spirits making a stronger impression on the fibres of a weakly habit than of a robust one. Strong vigorous men see an execution without much concern, while women of nicer texture are struck with horror and consternation. This sensibility in them must of consequence be communicated to all parts of the body; and, as the fibres of the child in the womb are incomparably finer than those of the mother, the course of the animal spirits must in consequence produce greater alterations. Hence, every stroke given to the criminal forcibly affected the imagination of the woman, and, by a kind of counter-stroke, the delicate, tender frame of the child.

Such is the reasoning of an ingenious man upon a fact, the veracity of which many since have called in question. They have allowed, indeed, that such a child might have been produced, but have denied the cause of its deformity. "How could the imagination of the mother," say they, "produce such dreadful effects upon her child? She has no communication with the infant; she scarce touches it in any part; quite unaffected with her concerns, it sleeps in security, in a manner secluded by a fluid in which it swims, from her that bears it. With what a variety of deformities," say they, "would all mankind be marked, if all the vain and capricious desires of the mother were thus readily written upon the body of the child?" Yet, notwithstanding this plausible way of reasoning, I cannot avoid giving some credit to the variety of instances I have either read or seen upon this subject. If it be a prejudice, it is as old as the days of Aristotle, and to this day as strongly believed by the generality of mankind as ever. It does not admit of a reason—and indeed I can give none—even why the child should in any respect resemble the father or the mother. The fact we generally find to be so; but why it should take the particular print of the father's features in the womb, it is as hard to conceive as why it should be affected by the mother's imagination. We all know what a strong effect the imagination has on those parts in particular, without being able to assign a cause how this effect is produced; and why the imagination may not produce the same effect in marking the child that it does in forming it I see no reason. Those persons whose employment it is to rear up pigeons of different colours can breed them, as their expression is, to a feather. In fact, by properly pairing them they can give what colour they will to any feather in any part of the body. Were we to reason upon this fact, what could we say? Might it not be asserted that the egg, being distinct from the body of the female, cannot be influenced by it? Might it not be plausibly said, that there is no similitude between any part of the egg and any particular feather which we expect to propagate? And yet for all this the

fact is known to be true, and what no speculation can invalidate. In the same manner, a thousand various instances assure us that the child in the womb is sometimes marked by the strong affections of the mother. How this is performed we know not; we only see the effect, without any connexion between it and the cause. The best physicians have allowed it, and have been satisfied to submit to the experience of a number of ages; but many disbelieve it, because they expect a reason for every effect. This, however, is difficult to be given, while it is easy to appear wise by pretending credulity.

Among the number of monsters, dwarfs and giants are usually reckoned; though not, perhaps, with the strictest propriety, since they are no way different from the rest of mankind except in stature. It is a dispute, however, about words; and therefore scarce worth contending about. But there is a dispute of a more curious nature upon this subject—namely, whether there are races of people thus very diminutive or vastly large, or whether they be merely accidental varieties that now and then are seen in the country, in a few persons whose bodies some external cause has contributed to lessen or enlarge.

With regard to men of diminutive stature, Antiquity has been unanimous in asserting their national existence. Homer was the first to give us an account of the pigmy nation contending with the cranes; and what poetical licence might be supposed to exaggerate, Athenæus has attempted seriously to confirm by historical assertion. If we attend to these, we must believe that in the internal parts of Africa there are whole nations of pigmy beings not more than a foot in stature, who continually wage an unequal war with the birds and beasts that inhabit the plains in which they reside. Some of the ancients, however, and Strabo in particular, have supposed all these accounts to be fabulous; and have been more inclined to think this supposed nation of pigmies nothing more than a species of apes, well known to be numerous in that part of the world. With this opinion the moderns have all concurred; and that diminutive race which was described as human has long been degraded into a class of animals that resemble us but very imperfectly.

The existence, therefore, of a pigmy race of mankind being founded in error or in fable, we can expect to find men of diminutive stature only by accident among men of the ordinary size. Of these accidental dwarfs, every country and almost every village can produce numerous instances. There was a time when these unfavoured children of Nature were the peculiar favourites of the great; and no prince or nobleman thought himself completely attended unless he had a dwarf among the number of his domestics. These poor little men were kept to be laughed at, or to raise the barbarous pleasure of their masters by their contrasted inferiority. Even in England, as late as the times of King James I., the court was at one time furnished with a dwarf, a giant, and a jester. These the king often took a pleasure in opposing to each other, and often fomented quarrels among them, in order to be a concealed spectator of their animosity. It was a particular entertainment of the courtiers at that time to see little Geoffrey (for so the dwarf was called) ride round the lists, expecting his antagonist, and discovering in his actions all the marks of contemptible resolution.

It was in the same spirit that Peter of Russia, in the year 1710, celebrated a marriage of dwarfs. This monarch, though raised by his native genius far above a barbarian, was nevertheless still many degrees removed from actual refinement. His pleasures, therefore, were of the vulgar kind; and this was among the number. Upon a certain day, which he had ordered to be proclaimed several months before, he invited the whole body of his courtiers and all the foreign ambassadors to be present at the marriage of a pigmy man and woman. The preparations for the wedding were not only very

grand, but were executed in a style of barbarous ridicule. He ordered that all the dwarf men and women within two hundred miles should repair to the capital, and also insisted that they should be present at the ceremony. For this purpose he supplied them with proper vehicles; but he so contrived it, that one horse was seen carrying a dozen of them into the city at once, while the mob followed shouting and laughing from behind. Some of them were at first unwilling to obey an order which they knew was calculated to turn them into ridicule, and they did not come; but he soon obliged them to obey, and as a punishment enjoined that they should wait upon the rest at dinner. The whole company of dwarfs amounted to seventy, beside the bride and bridegroom, who were richly adorned, and in the extreme of fashion. For this little company in miniature everything was suitably provided; a low table, small plates, little glasses—in fact, everything was so fitted as if all things had been dwindled to their own standard. It was his great pleasure to see their gravity and their pride—the contention of the women for places and the men for superiority. This point he attempted to adjust, by ordering that the most diminutive should take the lead; but this bred disputes, for none would then consent to sit foremost. All this, however, being at last settled, dancing followed the dinner, and the ball was opened with a minuet by the bridegroom, who measured exactly three feet two inches high. In the end matters were so contrived, that this little company, who met together in gloomy pride and unwilling to be pleased, being at last familiarised to laughter, joined in the diversion, and became, as the journalist has it, exceedingly sprightly and entertaining.

But whatever may be the entertainment such guests might afford when united, I never found a dwarf capable of affording any when alone. I have at different times conversed with some of these that were exhibited at our fairs about town, and have ever found their intellect as contracted as their persons. They in general seemed to me to have faculties very much resembling those of children, and desires also of the same kind—being diverted with the same sports, and best pleased with such companions. Of all those I have seen, which may amount to five or six, the little man named Coan, who recently died at Chelsea, was the most intelligent and sprightly. I have heard him and the giant who sung at the theatres sustain a very ridiculous duet, to which they were taught to give great spirit. But this mirth and seeming sagacity were but assumed. Coan had by long habit been taught to look cheerful upon the approach of company; and his conversation was but the mere etiquette of a person that had been used to receive visitors. When driven out of his walk nothing could be more stupid or ignorant—nothing more dejected and forlorn. But we have a complete history of a dwarf very accurately related by Mr. Daubenton, which I will here take the liberty to translate.

This dwarf, whose name was Baby, was well known, having spent the greatest part of his life at Lunenville, in the palace of Stanislaus, the titular King of Poland. He was born in the village of Plaisne, in France, in the year 1741. His father and mother were peasants, both of good constitutions, and inured to a life of husbandry and toilsome labour. Baby, when born, weighed but a pound and a quarter. We are not informed of the dimensions of his body at that time; but we may conjecture they were very small, as he was presented on a plate to be baptized, and for a long time lay in a slipper. His mouth, although proportioned to the rest of his body, was not at that time large enough to take in the nipple, and he was therefore obliged to be suckled by a she-goat that was in the house; and that served as a nurse, attending to his cries with a kind of maternal fondness. He began to articulate some words when eighteen months old; and at two years he was able

to walk alone. He was then fitted with shoes that were about an inch and a half long. He was attacked with several acute disorders; but the small-pox was the only one which left any marks behind it. Until he was six years old he eat no other food but pulse, potatoes, and bacon. His father and mother were, from their poverty, incapable of affording him any better nourishment; and his education was little better than his food, being bred up among the rustics of the place. At six years old he was about fifteen inches high, and his whole body weighed but thirteen pounds. Notwithstanding this, he was well-proportioned and handsome; his health was good, but his understanding scarce passed the bounds of instinct. It was at that time that the King of Poland, having heard of such a curiosity, had him conveyed to Lunenburg, gave him the name of "Baby," and kept him in his palace.

Baby, having thus quitted the hard condition of a peasant to enjoy all the comforts and the conveniences of life, seemed to receive no alteration from his new way of living, either in mind or in person. He preserved the goodness of his constitution till about the age of sixteen, but his body seemed to increase very slowly during the whole time; and his stupidity was such, that all instructions were lost in improving his understanding. He could never be brought to have any sense of religion, nor even to show the least signs of a reasoning faculty. They attempted to teach him dancing and music, but in vain; he never could make anything of music; and as for dancing, although he beat time tolerably exact, yet he could never remember the figure, unless his dancing-master stood by to direct his motions. Notwithstanding a mind thus destitute of understanding, it was not without its passions; anger and jealousy harassed it at times; nor was he without desires of another nature.

At the age of sixteen Baby was twenty-nine inches tall; at this he rested; but having thus arrived at his acme, the alterations of puberty—or rather, perhaps, of old age—came fast upon him. From being very beautiful the poor little creature now became quite deformed; his strength quite forsook him—his back-bone began to bend—his head hung forward—his legs grew weak—one of his shoulders turned awry—and his nose grew disproportionably large. With his strength his natural spirits also forsook him; and, by the time he was twenty, he was grown feeble, decrepid, and marked with the strongest impressions of old age. It had been before remarked by some that he would die of old age before he arrived at thirty; and, in fact, by the time he was twenty-two he could scarcely walk a hundred paces, being worn by the multiplicity of his years, and bent under the burthen of protracted life. In this year he died; a cold, attended with a slight fever, threw him into a kind of lethargy, which had a few momentary intervals, but he could scarce be brought to speak. However, it is asserted that in the five last days of his life he showed a clearer understanding than in his times of best health; but at length he died, after enduring great agonies, in the twenty-second year of his age.

Opposite to this accidental diminution of the human race is that of its extraordinary magnitude. Concerning the reality of a nation of giants there have been many disputes among the learned. Some have affirmed the probability of such a race; and others as warmly have denied the possibility of their existence. But it is not from any speculative reasonings upon a subject of this kind that information is to be obtained; it is not from the disputes of the scholar, but the labours of the enterprising, that we are to be instructed in this inquiry. Indeed, nothing can be more absurd than what some learned men have advanced upon this subject. It is very unlikely, says Grew, that there should either be dwarfs or giants; or if such, they cannot be fitted for the usual enjoyment of life and reason. Had man been born a

dwarf, he could not have been a reasonable creature; for to that end he must have a jolt head, and then he would not have body and blood enough to supply his brain with spirits; or if he had a small head proportionable to his body, there would not be brain enough for conducting life. But it is still worse with giants; and there could never have been a nation of such, for there would not be food enough found in any country to sustain them; or if there were beasts sufficient for this purpose, there would not be grass enough for their maintenance. But what is still more, add others, giants could never be able to support the weight of their own bodies; since a man of ten feet high must be eight times as heavy as one of the ordinary stature; whereas he has but twice the size of muscles to support such a burden, and consequently would be overloaded with the weight of his own body. Such are the theories upon this subject, and they require no other answer than that experience proves them both to be false. Dwarfs are found capable of life and reason; and giants are seen to carry their own bodies. We have several accounts from mariners that a nation of giants actually exists; and mere speculation should never induce us to doubt their veracity.

Ferdinand Magellan was the first who discovered this race of people along the coast towards the extremity of South America. Magellan was a Portuguese of noble extraction, who, having long behaved with great bravery under Albuquerque, the conqueror of India, was treated with neglect by the court upon his return. Applying, therefore, to the King of Spain, he was entrusted with the command of five ships to subdue the Molucca Islands, upon one of which he was slain. It was in his voyage thither that he happened to winter in St. Julian's Bay, an American harbour forty-nine degrees south of the line. In this desolate region, where nothing was seen but objects of terror, where neither trees nor verdure dress the face of the country, they remained for some months without seeing any human creature. They had judged the country to be utterly uninhabitable; when one day they saw approaching, as if it had been dropped from the clouds, a man of enormous stature, dancing and singing, and putting dust upon his head, as they supposed in token of peace. This overture for friendship was, by Magellan's command, quickly answered by the rest of his men; and the giant, approaching, testified every mark of astonishment and surprise. He was so tall that the Spaniards only reached his waist; his face was broad, his colour brown, and painted over with a variety of tints; each cheek had the resemblance of a heart drawn upon it; his hair was approaching to whiteness; he was clothed in skins, and armed with a bow. Being treated with kindness, and dismissed with some trifling presents, he soon returned with many more of the same stature—two of whom the mariners decoyed on ship-board. Nothing could be more gentle than they were in the beginning; they considered the fetters that were preparing for them as ornaments, and played with them like children with their toys; but when they found for what purpose they were intended they instantly exerted their amazing strength, and broke them in pieces with little effort. This account, with a variety of other circumstances, has been confirmed by succeeding travellers: Herrera, Sebald Wert, Oliver Van Noort, and James le Maire, all correspond in confirming the fact, although they differ in many particulars as to their respective descriptions. The last voyager we have had who has seen this enormous race is Commodore Byron. I have talked with the person who first gave the relation of that voyage, and who was the carpenter of the commodore's ship: he was a sensible, well-informed man, and I believe extremely faithful. By him I was assured of the truth of his relation; and this account has since been confirmed by one or two publications, in all which the particulars are pretty nearly the same. One of the

circumstances which most puzzled me to reconcile to probability was that of the horses on which they are described as riding down to the shore. We know the American horse to be of European breed, and in some measure to be degenerated from the original. I was at a loss, therefore, to account how a horse of not more than fourteen hands high was capable of carrying a man of nine feet; or, in other words, an animal almost as large as itself. But the wonder will cease when we consider that so small a beast as an ass will carry a man of ordinary size tolerably well; and the proportion between this and the former instances is nearly exact. We can no longer, therefore, refuse our assent to the existence of this gigantic race of mankind; in what manner they are propagated, or under what regulations they live, is a subject that remains for future investigation. It should appear, however, that they are a wandering nation, changing their abode with the course of the sun, and shifting their situation for the convenience of food, climate, or pasture.

This race of giants are described as possessed of great strength; and, no doubt, they are very different from those accidental giants that are to be seen in different parts of Europe. Stature with these seems rather their infirmity than their pride, and adds to their burthen without increasing their strength. Of those I have seen, the generality were ill-formed and unhealthful—weak in their persons, or incapable of exerting what strength they were possessed of. The same defects of understanding that attended those of suppressed stature were found in those who were thus overgrown; they were heavy, phlegmatic, stupid, and inclined to sadness. Their numbers, however, are but few; and it is thus kindly ordered by Providence, that as the middle state is the best fitted for happiness, so the middle ranks of mankind are produced in the greatest variety.

However, mankind seems naturally to have a respect for men of extraordinary stature; and it has been a supposition of long standing that our ancestors were much taller, as well as much more beautiful, than we. This has been, indeed, a theme of poetical declamation from the beginning; and man was scarce formed when he began to deplore an imaginary decay. Nothing is more natural than this progress of the mind, in looking up to antiquity with reverential wonder. Having been accustomed to compare the wisdom of our fathers with our own in early imbecility, the impression of their superiority remains when they no longer exist, and when we cease to be inferior. Thus the men of every age consider the past as wiser than the present; and the reverence seems to accumulate as our imaginations ascend. For this reason we allow remote antiquity many advantages without disputing their title: the inhabitants of uncivilised countries represent them as taller and stronger; and the people of a more polished nation as more healthy and more wise. Nevertheless, these attributes seem to be only the prejudices of ingenuous minds—a kind of gratitude, which we hope in turn to receive from posterity. The ordinary stature of men, Mr. Derham observes, is in all probability the same now as at the beginning. The oldest measure we have of the human figure is in the monument of Cheops, in the first pyramid of Egypt. This must have subsisted many hundred years before the time of Homer, who is the first that deplores the decay. This monument, however, scarce exceeds the measure of our ordinary coffins; the cavity is no more than six feet long, two feet wide, and deep in about the same proportion. Several mummies, also, of a very early age, are found to be only of the ordinary stature; and show that, for these three thousand years at least, men have not suffered the least diminution. We have many corroborating proofs of this in the ancient pieces of armour which are dug up in different parts of Europe. The brass helmet dug up at Medauro fits one of our men, and yet is allowed to have

been left there at the overthrow of Asdrubal. Some of our finest antique statues, which we learn from Pliny and others to be exactly as large as life, still continue to this day remaining monuments of the superior excellence of their workmen indeed, but not of the superiority of their stature. We may conclude, therefore, that men have been in all ages pretty much of the same size they are at present; and that the only difference must have been accidental, or perhaps national.

As to the superior beauty of our ancestors, it is not easy to make the comparison; beauty seems a very uncertain charm, and frequently is less in the object than in the eye of the beholder. Were a modern lady's face formed exactly like the Venus of Medicis or the Sleeping Vestal, she would scarce be considered beautiful except by the lovers of antiquity—whom of all her admirers, perhaps, she would be least desirous of pleasing. It is true that we have some disorders among us which disfigure the features, and from which the ancients were exempt; but it is equally true that we are without some that were common amongst them, and which were equally deforming. As for their intellectual powers, these also were probably the same as ours. We excel them in the sciences, which may be considered as a history of accumulated experience; and they excel us in the poetic arts, as they had the first rising of all the striking images of Nature.

## CHAP. XIII.

### OF MUMMIES, WAX-WORKS, ETC.

Man is not content with the usual term of life, but he is willing to lengthen out his existence by art; and although he cannot prevent death, he tries to obviate his dissolution. It is natural to attempt to preserve the most trifling relics of what has long given us pleasure; nor does the mind separate from the body without a wish that even the wretched heap of dust it leaves behind may yet be remembered. The embalming practised in various nations probably had its rise in this fond desire; an urn filled with ashes among the Romans served as a pledge of continuing affection; and even the grassy graves in our own church-yards are raised above the surface, with the desire that the body below should not be wholly forgotten. The soul, ardent after eternity itself, is willing to procure even for the body a prolonged duration.

But of all nations the Egyptians carried this art to the highest perfection; as it was a principle of their religion to suppose that the soul continued only coeval to the duration of the body, they tried every art to extend the one by preventing the dissolution of the other. In this practice they were exercised from the earliest ages; and the mummies they have embalmed in this manner continue in great numbers to the present day. We are told in Genesis, that Joseph, seeing his father expire, gave orders to his physicians to embalm the body, which they executed in the compass of forty days, the usual time of embalming. Herodotus, also, the most ancient of the profane historians, gives us a copious detail of this art, as it was practised in his time among the Egyptians. There are certain men among them, says he, who practise embalming as a trade, which they perform with all possible expedition. In the first place they draw out the brain through the nostrils, with irons adapted to this purpose; and in proportion as they evacuate it in this manner they fill up the cavity with aromatics: they next cut open the belly, near the sides, with a sharpened stone, and take out the entrails, which they cleanse, and wash in palm oil: having performed this operation, they roll them in aromatic powder, fill them with myrrh, cassia, and other perfumes, except incense, and replace

them, sewing up the body again. After these precautions they salt the body with nitre, and keep it in the salting-place for seventy days, it not being permitted to preserve it so any longer. When the seventy days are accomplished, and the body washed once more, they twathe it in bands made of linen, which have been dipt in a gum the Egyptians use instead of salt. When the friends have taken back the body they make a hollow trough, something like the shape of a man, in which they place the body; and this they enclose in a box, preserving the whole as a most precious relic placed against the wall. Such are the ceremonies used with regard to the rich; as for those who are contented with an humbler preparation, they treat them as follows:—They fill a syringe with an odoriferous liquor extracted from the cedar-tree, and, without making an incision, inject it up the body of the deceased, and then keep it in nitre as long as in the former case. When the time is expired, they evacuate the body of the cedar liquor which had been injected; and such is the effect of this operation, that the liquor dissolves the intestines and brings them away; the nitre also serves to eat away the flesh, and leaves only the skin and the bones remaining. This done, the body is returned to the friends, and the embalmer takes no farther trouble about it. The third method of embalming those of the meanest condition is merely by purging and cleansing the intestines by frequent injections, and preserving the body for a similar term in nitre, at the end of which it is restored to the relations.

Diodorus Siculus also makes mention of the manner in which these embalmings are performed. According to him there were several officers appointed for this purpose. The first of them, who was called the scribe, marked those parts of the body on the left side which were to be opened; the cutter made the incision; and one of those that were to salt it drew out all the bowels, except the heart and the kidneys; another washed them in palm-wine and odoriferous liquors; afterwards they anointed for above thirty days with cedar gum, myrrh, cinnamon, and other perfumes. These aromatics preserved the body entire for a long time, and gave it a very agreeable odour. It was not in the least disfigured by this preparation; after which it was returned to the relations, who kept it in a coffin placed upright against the wall.

Most of the modern writers who have treated on this subject have merely repeated what has been said by Herodotus; and if they add anything of their own it is but merely from conjecture. Dumont observes, that it is very probable that aloes, bitumen, and cinnamon make a principal part of the composition which is used on this occasion: he adds that, after embalming, the body is put into a coffin made of the sycamore-tree, which is almost incorruptible. Mr. Grew remarks, that in an Egyptian mummy in the possession of the Royal Society, the preparation was so penetrating as to enter into the very substance of the bones, and rendered them so black that they seemed to have been burnt. From this he is induced to believe that the Egyptians had a custom of embalming their dead by boiling them in a kind of liquid preparation, until all the aqueous parts of the body were exhaled away, and until the oily or gummy matter had penetrated throughout. He proposes, in consequence of this, a method of macerating, and afterwards of boiling the dead body in oil of walnut.

I am, for my own part, of opinion that there were several ways of preserving dead bodies from putrefaction; and that this would be no difficult matter, since different nations have all succeeded in the attempt. We have an example of this kind among the Guanches, the ancient inhabitants of the island of Teneriffe. Those who survived the general destruction of this people by the Spaniards, when they conquered this island, informed them that the art of embalming was still preserved there, and that there was a tribe of priests among them pos-

sessed of the secret, which they kept concealed as a sacred mystery. As the greatest part of the nation was destroyed the Spaniards could not arrive at a complete knowledge of this art, but only found out a few particulars. Having taken out the bowels, they washed the body several times in a lye made of the dried bark of the pine-tree, warmed during the summer by the sun, or by a stove in the winter. They afterwards anointed it with butter or the fat of bears, which they had previously boiled with odoriferous herbs, such as sage and lavender. After this unction they suffered the body to dry, and then repeated the operation as often as it was necessary, until the whole substance was impregnated with the preparation. When it was become very light it was then a certain sign it was fit and properly prepared. They then rolled it up in the dried skins of goats, which, when they had a mind to save expense, they suffered to remain with the hair still growing upon them. Purchas assures us that he has seen mummies of this kind in London; and mentions the name of a gentleman who had seen several of them in the island of Teneriffe which were supposed to have been two thousand years old, but without any certain proofs of such great antiquity. This people, who probably came first from the coast of Africa, might have learned this art from the Egyptians, as there was a traffic carried on from thence into the most internal parts of Africa.

Both Acosta and Garcilasso de la Vega make no doubt but that the Peruvians understood the art of preserving their dead for a very long space of time. They assert their having seen the bodies of several incas that were perfectly preserved. They still preserved their hair and their eye-brows; but they had eyes made of gold put in the places of these taken out. They were clothed in their usual habits, and seated in the manner of the Indians, their arms placed on their breasts. Garcilasso touched one of their fingers, and found it apparently as hard as wood; and the whole body was not heavy enough to over-burthen a weak man who should attempt to carry it away. Acosta presumes that these bodies were embalmed with bitumen, of which the Indians knew the properties. Garcilasso, however, is of a different opinion, as he saw nothing bituminous about them; but he confesses that he did not examine them particularly, and he regrets his not having inquired into the methods used for that purpose. He adds that, being a Peruvian, his countrymen would not have scrupled to inform him of the secret if they really had it still among them.

Garcilasso, thus being ignorant of the secret, makes use of some inductions to throw light upon the subject; he asserts that the air is so dry and so cold at Cusco that flesh dries their like wood without corrupting; and he is of opinion that they dried the body in snow before they applied the bitumen: he adds, that in the time of the incas they usually dried the flesh which was designed for the use of the army; and that, when they had lost their humidity, they might be kept without salt or any other preparation.

It is said that at Spitzbergen, which lies within the arctic circle, and consequently in the coldest climate, bodies never corrupt, nor suffer any apparent alteration, even though buried for thirty years: nothing corrupts or putrefies in that climate; the wood which has been employed in building those houses where the train-oil is separated appears as fresh as on the day when it was first cut.

If excessive cold, therefore, be thus capable of preserving bodies from corruption, it is not less certain that a great degree of dryness produced by heat produces the same effect. It is well known that the men and animals that are buried in the sands of Arabia quickly dry up, and continue in preservation for several ages as if they had been actually embalmed. It has often happened that whole caravans have perished in crossing those deserts, either by the burning winds that infect them or

by the sands which are raised by the tempest, and overwhelm every creature in certain ruin. The bodies of those persons are preserved entire; and they are often found in this condition by some accidental passenger. Many authors, both ancient and modern, make mention of such mummies as these; and Shaw says that he has been assured that numbers of men, as well as other animals, have thus been preserved for times immemorial in the burning sands of Saibah, which is a place, he supposes, situate between Rasem and Egypt.

The corruption of dead bodies being entirely caused by the fermentation of the humours, whatever is capable of hindering or retarding this fermentation will contribute to their preservation. Both heat and cold, though so contrary in themselves, produce similar effects in this particular by drying up the humours—the cold in condensing and thickening them, and the heat in evaporating them before they have time to act upon the solids. But it is necessary that these extremes should be constant; for if they succeed each other so as that cold shall follow heat, or dryness humidity, it must then necessarily happen that corruption must ensue. However, in temperate climates there are natural causes capable of preserving dead bodies; among which we may reckon the qualities of the earth in which they are buried. If the earth be drying and astringent it will inabite the humidity of the body; and it may be probably for this reason that the bodies buried in the monastery of the Cordeliers at Thoulouse do not putrefy, but dry in such a manner that they may be lifted up by one arm.

The gums, resins, and bitumens with which dead bodies are embalmed keep off the impressions which they would else receive from the alteration of the temperature of the air; and still more, if a body thus prepared be placed in a dry and burning sand, the most powerful means will be united for its preservation. We are not to be surprised, therefore, at what we are told by Chardin of the country of Choresan, in Persia. The bodies which have been previously embalmed and buried in the sands of that country, as he assures us, are found to petrify; or, in other words, to become extremely hard, and are preserved for several ages. It is asserted that some of them have continued for a thousand years.

The Egyptians, as has been mentioned above, swathed the body with linen bands, and enclosed it in a coffin; however, it is probable that with all these precautions they would not have continued till now if the tombs or pits in which they were placed had not been dug in a dry chalky soil, which was not susceptible of humidity, and which was, besides, covered over with a dry sand of several feet thickness.

The sepulchres of the ancient Egyptians subsist to this day. Most travellers who have been in Egypt have described those of ancient mummies, and have seen the mummies interred there. These catacombs are within two leagues of the ruins of this city, nine leagues from Grand Cairo, and about two miles from the village of Zaccara. They extend from thence to the Pyramids of Pharaoh, which are about eight miles distant. These sepulchres lie in a field covered with a fine running sand of a yellowish colour. The country is dry and hilly; the entrance to the tomb is choked up with sand; there are many open, but several more that are still concealed. The inhabitants of the neighbouring village have no other commerce or method of subsisting but by seeking out mummies, and selling them to such strangers as happen to be at Grand Cairo. This commerce some years ago was not only a very common but a very gainful one. A complete mummy was often sold for twenty pounds; but it must not be supposed that it was bought at such a high price from a mere passion for antiquity; there were much more powerful motives for this traffic. Mummy at that time made a considerable article in medicine; and a thousand imaginary virtues were ascribed to it for the cure of most disorders, particularly

of the paralytic kind. There was no shop, therefore, without mummy in it; and no physician thought he had properly treated his patient without adding this to his prescription. Induced by the general repute in which this supposed drug was held at that time, several Jews, both of Italy and France, found out the art of imitating mummies so exactly, that they for a long time deceived all Europe. This they did by drying dead bodies in ovens, after having prepared them with myrrh, aloes, and bitumen. Still, however, the request for mummies continued, and a variety of cures were daily ascribed to them. At length, Parseus wrote a treatise on their total inefficacy in physic; and showed their abuse in loading the stomach to the exclusion of more efficacious medicines. From that time, therefore, their reputation began to decline; the Jews discontinued their counterfeits, and the trade returned entire to the Egyptians when it was no longer of value. The industry of seeking after mummies is now totally relaxed, their price merely arbitrary, and just what the curious are willing to give.

In seeking for mummies they first clear away the sand, which they may do for weeks together without finding what is wanted. Upon coming to a little square opening of about eighteen feet in depth, they descend into it by holes for the feet placed at proper intervals, and there they are sure of finding what they seek for. These caves, or wells as they call them, are hollowed out of a white freestone, which is found in all this country a few feet below the covering of the sand. When one gets to the bottom of these, which are sometimes forty feet below the surface, there are several square openings on each side into passages ten or fifteen feet wide, and these lead to chambers fifteen or twenty feet square. These are all hewn out of the rock; and in each of the catacombs are to be found several of these apartments communicating with each other. They extend a great way underground, so as to be under the city of Memphis, and in a manner to undermine its environs.

In some of the chambers the walls are adorned with figures and hieroglyphics; in others, the mummies are found in tombs round the apartment hollowed out in the rock. These tombs are upright, and cut into the shape of a man with his arms stretched out. There are others found, and these in the greatest number, in wooden coffins or in clothes covered with bitumen. These coffins or wrappers are covered all over with a variety of ornaments. There are some of them painted and adorned with figures, such as that of Death and the leaden seals, on which several characters are engraven. Some of the coffins are carved into the human shape; but the head alone is distinguishable; the rest of the body is all of a piece, and terminated by a pedestal, while there are some with their arms hanging down; and it is by these marks that the bodies of persons of rank are distinguished from those of the meaner order. These are generally found lying on the floor without any profusion of ornaments; and in some chambers the mummies are found indiscriminately piled upon each other, and buried in the sand.

Many mummies are found lying on their backs, their heads turned to the north, and the hands placed on the belly. The bands of linen with which these are swathed are more than a thousand yards long; and in consequence the number of circumvolutions they make about the body must have been amazing. These were performed by beginning at the head and ending at the feet; but they contrived it so as to avoid covering the face. However, when the face is entirely uncovered it moulders into dust immediately upon the admission of the air. When, therefore, it is preserved entire, a slight covering of cloth is so disposed over it as that the shape of the eyes, the nose, and the mouth are seen under it. Some mummies have been found with a long beard, and hair that reached down to the mid-leg, nails of a surprising length, and some gilt, or at least painted of a gold colour. Some are

found with bands upon their breast, covered with hieroglyphics in gold, silver, or in green; and some with tutelary idols and other figures of jasper within their body. A piece of gold, also, has often been found under their tongues, of about two pistoles value; and for this reason the Arabians spoil all the mummies they meet with in order to get at the gold.

But though art or accident has thus been found to preserve dead bodies entire, it must by no means be supposed that it is capable of preserving the exact form and lineaments of the deceased person. Those bodies which are found dried away in the deserts or in some particular church-yards are totally deformed, and scarce any lineaments remain of their external structure. Nor are the mummies preserved by embalming in a better condition. The flesh is dried away, hardened, and hidden under a variety of bandages; the bowels, as we have seen, are totally removed; and from hence, in the most perfect of them we see only a shapeless mass of skin discoloured; and even the features are scarce distinguishable. The art is therefore an effort rather of preserving the substance than the likeness of the deceased, and has consequently not been brought to its highest pitch of perfection. It appears from a mummy, not long since dug up in France, that the art of embalming was more completely understood in the western world than even in Egypt. This mummy, which was dug up at Auvergne, was an amazing instance of their skill, and is one of the most curious relics in the art of preservation. As some peasants in that part of the world were digging in a field near Rion, within about twenty-six paces of the highway, between that and the river Artier, they discovered a tomb about a foot and a half beneath the surface. It was composed only of two stones, one of which formed the body of the sepulchre and the other the cover. This tomb was of freestone, seven feet and a half long, three feet and a half broad, and about three feet high. It was of rude workmanship; the cover had been polished, but was without figure or inscription: within this tomb was placed a leaden coffin four feet seven inches long, fourteen inches broad, and fifteen high. It was not made coffin-fashion, but oblong, like a box, equally broad at both ends, and covered with a lid that fitted on like a snuff-box without a hinge. This cover had two holes in it, each of about two inches long, and very narrow, filled with a substance resembling butter; but for what purpose intended remains unknown. Within this coffin was a mummy in the highest and most perfect preservation. The internal sides of the coffin were filled with an aromatic substance, mingled with clay. Round the mummy was wrapped a coarse cloth, in form of a napkin; under this were two shirts, or shrouds, of the most exquisite texture; beneath these was a bandage, which covered all parts of the body like an infant in swaddling clothes; still under this general bandage there was another, which went particularly round the extremities, the hands, and the legs. The head was covered with two caps; the feet and hands were without any particular bandages; and the whole body was covered with an aromatic substance an inch thick. When these were removed, and the body exposed naked to view, nothing could be more astonishing than the preservation of the whole, and the exact resemblance it bore to a body that might have died a day or two before. It appeared well proportioned, except that the head was rather large and the feet small. The skin had all the pliancy and colour of a body lately dead; the visage, however, was of a brownish hue. The belly yielded to the touch; all the joints were flexible, except those of the legs and feet; the fingers stretched forth of themselves when bent inwards. The nails still continued entire; and all the marks of the joints, both in the fingers, the palms of the hands, and the soles of the feet, remained perfectly visible. The bones of the arms and legs were soft and pliant; but, on the contrary, those of the skull preserved their rigidity; the hair, which only

covered the back of the head, was of a chestnut colour, and about two inches long. The pericranium at top was separated from the skull by an incision, in order to open it for the introducing proper aromatics in the place of the brain, where they were found mixed with clay. The teeth, the tongue, and the ears were all preserved in perfect form. The intestines were not taken out of the body, but remained pliant and entire as in a fresh subject; and the breast was made to rise and fall like a pair of bellows. The embalming preparation had a very strong and pungent smell, which the body preserved for more than a month after it was exposed to the air. This odour was perceived wherever the mummy was laid; although it remained there but a short time, it was even pretended that the peasants of the neighbouring villages were incommoded by it. If you touched either the mummy or any part of the preparation, the hands smelled of it for several hours after, although washed with water, spirit of wine, or vinegar. This mummy, having remained exposed for some months to the curiosity of the public, began to suffer some mutilations. A part of the skin of the forehead was cut off; the teeth were drawn out; and some attempts were made to pull away the tongue. It was therefore put into a glass case, and shortly after transmitted to the King of France's cabinet at Paris.

There are many reasons to believe this to be the body of a person of the highest distinction; however, no marks remain to assure us either of the quality of the person or the time of his decease. There are only to be seen some irregular figures on the coffin, one of which represents a kind of star. There were also some singular characters upon the bandages, which were totally defaced by those who had torn them away. However, it would seem that it had remained for several ages in this state, since the first years immediately succeeding the interment are usually those in which the body is most liable to decay. It appears, also, to be a much more perfect method of embalming than that of the Egyptians—as in this the flesh continues with its natural elasticity and colour, the bowels remain entire, and the joints have almost the pliancy which they had when the person was alive. Upon the whole, it is probable that a much less tedious preparation than that used by the Egyptians would have sufficed to keep the body from putrefaction, and that an injection of petroleum inwardly and a layer of asphaltum without would have been sufficient to make a mummy; and it is remarkable that Auvergne, where this was found, affords these two substances in sufficient plenty. This art, therefore, might be brought to greater perfection than it has hitherto arrived at were it worth preserving. But mankind have long since grown wiser in this respect, and think it foolish to keep by them a deformed carcass, which, instead of aiding their magnificence, must only serve to mortify their pride.

#### CHAP. XIV.

##### OF ANIMALS.

Leaving man, we now descend to the lower ranks of Animated Nature, and prepare to examine the life, manners, and characters of these our humble partners in the creation. But in such a wonderful variety as is diffused around us, where shall we begin? The number of beings endued with life as well as ourselves seems at first view infinite. Not only the forest, the waters, and the air teem with animals of various kinds, but almost every vegetable and every leaf has millions of minute inhabitants, each of which fills up the circle of its allotted life, and some of which are found objects of the greatest curiosity. In this seeming exuberance of animals it is

natural for ignorance to lie down in hopeless uncertainty, and to declare what requires labour to particularise to be utterly inscrutable. It is otherwise, however, with the active and searching mind; no way intimidated with the immense variety, it begins the task of numbering, grouping, and classing all the various kinds that fall within its notice—finds every day new relations between the several parts of the creation—acquires the art of considering several at a time under one point of view—and at last begins to find that the variety is neither so great nor so inscrutable as was at first imagined. As in a clear night the number of the stars seems infinite, yet, if we sedulously attend to each in its place, and regularly class them, they will soon be found to diminish and come within a very scanty computation.

Method is one of the principal helps in natural history, and without it very little progress can be made in this science. It is by that alone we can hope to dissipate the glare, if I may so express it, which arises from a multiplicity of objects at once presenting themselves to the view. It is method that fixes the attention to one point, and leads it, by slow and certain degrees, to leave no part of Nature unobserved.

All naturalists, therefore, have been very careful in adopting some method of classing or grouping the several parts of Nature; and some have written books of natural history with no other view. These methodical divisions some have treated with contempt, not considering that books in general are written with opposite views—some to be read and some only to be occasionally consulted. The methodists in natural history seem to be content with the latter advantage, and have sacrificed to order alone all the delights of the subject—all the arts of heightening, awakening, or continuing curiosity. But they certainly have the same use in science that a dictionary has in language; but with this difference—that in a dictionary we proceed from the name to the definition; in a system of natural history we proceed from the definition to find out the thing. Without the aid of System, Nature must still have lain undistinguished, like furniture in a lumber-room; everything we wish for is there, indeed; but we know not where to find it. If, for instance, in a morning excursion I find a plant or an insect, the name of which I desire to learn—or, perhaps, am curious to know whether already known—in this inquiry I can expect information only from one of these systems, which, being couched in a methodical form, quickly directs me to what I seek for. Thus we will suppose that our inquirer has met with a spider, and that he has never seen such an insect before. He is taught by the writer of a system to examine whether it has wings, and he finds that it has none. He therefore has to look for it among the wingless insects, or “*aptera*,” as Linnaeus calls them; he then is to see whether the head and breast make one part of the body, or are disunited; he finds they make one: he is then to reckon the number of feet and eyes, and he finds that it has eight of each. The insect, therefore, must be either a scorpion or a spider; but he lastly examines its feelers, which he finds clavated or clubbed; and by all these marks he at length discovers it to be a spider. Of spiders there are forty-seven sorts; and by reading the description of each the inquirer will learn the name of that which he desires to know. With the name of the insect he is also directed to those authors that have given any account of it, and the page where that account is to be found; by this means he may know at once what has been said of that animal by others, and what there is of novelty in the result of his own researches.

From hence it will appear how useful those systems in natural history are to the inquirer; but having given them all their merit, it would be wrong not to observe that they have in general been much abused. Their authors in general seem to think that they are improvers of natural history, when in reality they are nothing but

guides; they seem to boast that they are adding to our knowledge, while they are only arranging it. These authors also seem to think that the reading of their works and systems is the best method to attain a knowledge of Nature; but, setting aside the impossibility of getting through whole volumes of a long dry catalogue, the multiplicity of whose contents is too great for even the strongest memory, such works rather tell us the name than the history of the creature we desire to inquire after. In these dreary pages, every insect or plant that has a name makes as distinguished a figure as the most wonderful or the most useful. The true end of studying Nature is to make a just selection, to find those parts of it which most conduce to our pleasure or convenience, and to leave the rest in neglect. But these systems, employing the same degree of attention upon all, give us no opportunities of knowing which most deserves attention; and he who has derived his knowledge from such systems only has his memory confounded with a number of trifling or minute particulars, which it should be his business and his study to forget. These books, as was said before, are useful to be consulted, but are quite unnecessary to be read: no inquirer after Nature should be without one of them—and without any doubt Linnaeus deserves the preference.

Another fault in almost all these systematic writers—and that which leads me to the subject of the present chapter—is, that seeing the necessity of methodical distribution in some parts of Nature they have introduced it into all. Finding the utility of arranging plants, birds, or insects, they have also arranged quadrupeds with the same assiduity; and although the number of these is so few as not to exceed two hundred, they have darkened the subject with distinctions and divisions, which only serve to puzzle and perplex. Method is only useful in perspicuity, where the subject is either dark or copious; but with regard to quadrupeds the number is but few; many of them we are well acquainted with by habit—and the rest may readily be known without any method. In treating of such, therefore, it would be useless to confound the reader with a multiplicity of divisions; as quadrupeds are conspicuous enough to obtain the second rank in Nature, it becomes us to be at least acquainted with the names of them all. However, as there are naturalists who have gained a name from the excellence of their methods in classing these animals, some readers may desire to have a knowledge of what has been laboriously invented for their instruction. I will just take leave, therefore, to mention the most applauded methods of classing animals, as adopted by Ray, Klein, and Linnaeus; for it often happens that the terms which have been long used in science, though frivolous, become by prescription a part of the science itself.

Ray, after Aristotle, divides all animals into two kinds—those which have blood and those which are bloodless. In the last class he places all the insect tribes: the former he divides into such as breathe through the lungs and such as breathe through gills; these last comprehend the fishes. In those which breathe through the lungs some have the heart composed of two ventricles, and some have it of one. Of the last are all animals of the cetaceous kind, all oviparous quadrupeds, and serpents. Of those that have two ventricles some are oviparous, which are the birds; and some viviparous, which are quadrupeds. The quadrupeds he divides into such as have a hoof and such as are claw-footed. Those with the hoof he divides into such as have it undivided, such as have it cloven, and such as have the hoof divided into more parts, as the rhinoceros and hippopotamus. Animals with the cloven hoof he divides into such as chew the cud, such as the cow and the sheep; and such as are not ruminant, as the hog. He divides those animals that chew the cud into four kinds: the first have hollow horns, which they never shed, as the cow; the second is of a less species, and is of the “sheep” kind;

the third is of the goat kind; and the last, which have solid horns, and shed them annually, are of the deer kind. Coming to the claw-footed animals, he finds some with large claws resembling the fingers of the human hand; and these he makes the ape kind. Of the others, some have the foot divided in two, and have a claw to each division; these are the camel kind. The elephant makes a kind by itself, as its claws are covered over by a skin. The rest of the numerous tribe of claw-footed animals he divides into two kinds—the analagous, or such as resemble each other; and the anomalous, which differ from the rest. The analogous claw-footed animals are of two kinds: they have more than two cutting teeth in each jaw, such as the lion and the dog, which are carnivorous; or they have no more than two cutting teeth in each jaw: these are chiefly fed upon vegetables. The carnivorous kind are divided into the great and the little. The great carnivorous animals are divided into such as have a short snout, as the cat and the lion; and pointed, as the dog and the wolf. The little claw-footed carnivorous animals differ from the great, in having a proportionably smaller head and a slender body, which fit them for creeping into holes in pursuit of their prey, like worms; and they are therefore called the vermin kind.

We see, from this sketch of division and sub-division, how a subject, extremely delightful and amusing in itself, may be darkened and rendered disgusting. But notwithstanding, Ray seems to be one of the most simple distributors; and his method is still, and not without reason, adopted by many. Such as have been at the trouble to learn this method will certainly find it useful; nor would we be thought in the least to take from its merits; all we contend for is, that the same information may be obtained by a pleasanter and an easier method.

It was the great success of Ray's method that soon after produced such a variety of attempts in the same manner, but almost all less simple and more obscure. Mr. Klein's method is briefly as follows: he makes the power of changing place the characteristic mark of animals in general; and he takes their distinctions from their aptitude and fitness for such a change. Some change place by means of feet, or some similar contrivance; others have wings and feet; some can change place only in water, and have only fins; some go upon earth without any feet at all: some change place by moving their shell; and some move only at a certain time of the year. Of such, however, as do not move at all he takes no notice. The quadrupeds that move chiefly by means of four feet upon land he divides into two orders. The first are the hoofed kind; and the second the claw kind. Each of these orders is divided into four families—the first family of the hoof kind and the single hoofed, such as the horse, ass, &c.; the second family are such as have the hoof cloven into two parts, such as the cow, &c.; the third family have the hoof divided into three parts—and in this family is found only the rhinoceros; the fourth family have the hoof divided into five parts—and in this is only to be found the elephant. With respect to the clawed kind, the first family comprehends those that have but two claws on each foot, as the camel; the second family have three claws, the third four, and the fourth five. This method of taking the distinctions of animals from the organs of motion is ingenious; but it is at the same time incomplete; and, besides, the divisions into which it must necessarily fall is inadequate; since, for instance, in his family with two claws there is but one animal; whereas, in his family with five claws there are above a hundred.

Brisson, who has laboured at this subject with great accuracy, divides Animated Nature into nine classes—namely, quadrupeds; cetaceous animals, or those of the whale kind; birds; reptiles, or those of the serpent kind; cartilaginous fishes; spinous fishes; shelled animals;

insects; and worms. He divides the quadrupeds into eighteen orders, and takes their distinctions from the number and form of their teeth.

But of all those systems that have been adopted and admired Linnaeus is the foremost; as, with a studied brevity, his system comprehends the greatest variety in the smallest space.

According to him, the first distinction of animals is to be taken from their internal structure. Some have the heart with two ventricles, and hot red blood—namely, quadrupeds and birds. The quadrupeds are viviparous, and the birds oviparous.

Some have the heart with one ventricle, and cold red blood; namely, amphibias and fishes. The amphibias are furnished with lungs—the fishes with gills.

Some have the heart with one ventricle, and cold white serum—namely, insects and worms; the insects have feelers, and the worms holders.

The distinctions of quadrupeds, or animals with paws as he calls them, are taken from their teeth. He divides them into seven orders, to which he gives names that are not easy of translation—Primates, or principals, with four cutting teeth in each jaw; Bruta, or brutes, with no cutting teeth; Ferae, or wild beasts, generally with six cutting teeth in each jaw; Glires, or dormice, with two cutting teeth both above and below; Pecora, or cattle, with many cutting teeth above and none below; Belluae, or beasts, with the fore-teeth blunt; Ceta, or those of the whale kind, with cartilaginous teeth. I have but just sketched out this system, as being in its own nature the closest abridgment; it would take many volumes to dilate it to its proper length. The names of the different animals and their classes alone make two thick octavo volumes; and yet nothing is given but the slightest description of each. I have also omitted all criticism upon the accuracy of the preceding systems. This has been done both by Buffon and Daubenton, not with less truth than humour; for they had too much good sense not to see the absurdity of multiplying the terms of science to no end, and disappointing our curiosity rather with a catalogue of Nature's varieties than a history of Nature.

Instead, therefore, of taxing the memory and taxing the patience with such a variety of divisions and subdivisions, I will take leave to class the productions of Nature in the most obvious, though not in the most accurate manner. In natural history, of all other sciences, there is the least danger of obscurity. In morals or in metaphysics every definition must be precise, because those sciences are built upon definitions; but it is otherwise in those subjects where the exhibition of the object itself is always capable of correcting the error. Thus it may often happen that in a lax system of natural history a creature may be ranked among quadrupeds that belongs more properly to the fish or the insect classes. But that can produce very little confusion, and every reader can thus make a system the most agreeable to his imagination. It will be of no manner of consequence whether we call a bird or an insect a quadruped, if we are careful in marking all its distinctions—the uncertainty in reasoning or thinking that those approximations of the different kinds of animals produce is but very small, and happens but very rarely; whereas the labour that naturalists have been at to keep the kinds asunder has been excessive. This in general has given birth to that variety of systems which we have just mentioned, each of which seems to be almost as good as the preceding.

Taking, therefore, this latitude, and using method only where it contributes to conciseness or perspicuity, we shall divide Animated Nature into four classes—namely, Quadrupeds, Birds, Fishes, and Insects. All these seem in general pretty well distinguished from each other by nature; yet there are several instances in which we can scarce tell whether it is a bird or quadruped.

rupted that we are about to examine—whether it is a fish or an insect that attracts our curiosity. Nature is varied by imperceptible gradations, so that no line can be drawn between any two classes of its productions, and no definition made to comprehend them all. However, the distinctions between these classes are sufficiently marked, and their encroachments upon each other are so rare, that it will be sufficient particularly to apprise the reader when they happen to be blended.

There are many quadrupeds that we are well acquainted with; and of those we do not know we shall form the most clear and distinct conceptions by being told wherein they differ and wherein they resemble those with which we are familiar. Each class of quadrupeds may be ranged under some one of the domestic kinds, that may serve for the model by which we are to form some kind of idea of the rest. Thus we may say that a tiger is of the cat kind and a wolf of the dog kind, because there are some rude resemblances between each; and a person who has never seen the wild animals will have some complete knowledge of their figure from the tame ones. On the contrary, I will not, as some systematic writers have done, say that a bat is of the human kind, or a hog of the horse kind, merely because there is some resemblance in their teeth or their paws;—for although this resemblance may be striking enough, yet a person who has never seen a bat or a hog will never form any just conception of either by being told of this minute similitude. In short, the method in classing quadrupeds should be taken from their most striking resemblances; and where these do not offer we should not force the similitude, but leave the animal to be described as a solitary species. The number of quadrupeds is so few, that, indeed, without any method whatever there is no greater danger of confusion.

All quadrupeds—the number of which, according to Buffon amounts to about two hundred—may be classed in the following manner:—

First, those of the Horse kind. This class contains the horse, the ass, and the Zebra. Of these none have horns, and their hoof is of one solid piece.

The second class are those of the Cow kind; comprehending the urus, the buffalo, the bison, and the bonasua. These have cloven hoofs, and chew the cud.

The third class is that of the Sheep kind; with cloven hoofs, and chewing the cud, like the former. In this is comprehended the sheep, the Goat, the Lama, the visigone, the gazelle, the guinea-deer, and all of a similar form.

The fourth class is that of the Deer kind, with cloven hoofs, and with solid horn that are shed every year. This class contains the elk, the rein-deer, the Stag, the buck, the roe-buck, and the axis.

The fifth class comprehends all those of the Hog kind, the peccari, and babyrouseas.

The sixth class is that numerous one of the Cat kind. This comprehends the cat, the lion, the panther, the leopard, the jaguar, the cougar, the jaguarete, the lynx, the ounce, and the catamountain. These are all carnivorous, and furnished with crooked claws, which they can sheath and unsheath at pleasure.

The seventh class is that of the Dog kind—carnivorous, and furnished with claws like the former, but which they cannot sheath. This class comprehends the dog, the wolf, the fox, the jackall, the issia, the hyena, the civetta, the gibel, and the genet.

The eighth class is that of the Weasel kind, with a long small body, with five toes or claws on each foot, the first of them separated from the rest like a thumb. This comprehends the weasel, the martin, the pole-cat, the ferret, the mangoust, the vanfire, the ermine, with all the varieties of the American mousettes.

The ninth class is that of the rabbit kind, with two large cutting teeth in each jaw. This comprehends the rabbit, the hare, the Guinea-pig, all the various species

of the squirrel, the dormouse, the marmotte, the rat, the mouse, the agouti, the paca, the aperea, and the tapeti.

The tenth class is that of the Hedge-hog kind, with claw feet, and covered with prickles, comprehending the hedge-hog, the porcupine, the couando, and the urson.

The eleventh class is that of the Tortoise kind, covered with a shell or scale. This comprehends the tortoise, the pangolin, and the phataguin.

The twelfth is that of the Otter, or amphibious kind, comprehending the otter, the beaver, the desman, the morse, and the seal.

The thirteenth class is that of the Ape and Monkey kinds, with hands and feet resembling hands.

The fifteenth class is that of winged quadrupeds, or the Bat kind, containing the bat, Flying squirrel, and some other varieties.

The animals which seem to approach no other kind, either in nature or in form, but to make each a distinct species in itself, are the following—the elephant, the rhinoceros, the hippopotamus, the cameopard, the camel, the bear, the badger, the tapir, the cabiai, the coati, the antbear, the tatau, and, lastly, the sloth.

All other quadrupeds whose names are not set down will be found among some of the above-mentioned classes, and referred to that which they most resemble. When, therefore, we are at a loss to know the name of any particular animal, by examining which of the known kinds it most resembles, either in shape or in hoofs or claws, and then examining the particular description, we shall be able to discover not only its name but its history. I have already said that all methods of this kind are merely arbitrary, and that Nature makes no exact distinction between her productions. It is hard, for instance, to tell whether we ought to refer the civet to the dog or the cat kind; but if we know the exact history of the civet, it is no great matter to which kind we shall judge it to bear the greatest resemblance. It is enough that a distribution of this kind excites in us some rude outlines of the make or some marked similitudes in the nature of these animals; but to know these with any precision, no system, nor even description, will serve, since the animal itself, or a good print of it, must be seen, and its history be read at length, before it can be said to be known. To pretend to say that we have an idea of a quadruped because we can call the number or the make of its teeth or its paws, is as absurd as if we should pretend to distinguish men by the buttons on their clothes. Indeed, it often happens that the quadruped itself can be but seldom seen—that many of the more rare kinds do not come into Europe above once in an age; and some of them have never been able to bear the removal. In such a case, therefore, there is no other substitute but a good print of the animal to give an idea of its figure; for no description whatsoever can answer this purpose so well. Mr. Locke, with his usual good sense, has observed that a drawing of the animal, taken from the life, is one of the best methods of advancing natural history; and yet most of our modern systematic writers are content rather with describing. Description, no doubt, will go some way towards giving an idea of the figure of an animal; but they are certainly much the longest way about, and, as they are usually managed, much the most obscure. In a drawing, we can at a single glance gather more instruction than by a day's painful investigation of methodical systems, where we are told the proportions with great exactness, and yet remain ignorant of the totality. In fact, this method of describing all things is a fault that has infected many of our books that treat on the meaner arts for this last age. They attempt to teach by words what is only to be learnt by practice and inspection: most of our dictionaries and bodies of arts and sciences are guilty of this error. Suppose, for instance, it be requisite to mention the manner of making shoes, it is plain that all the verbal instructions in the

world will never give an adequate idea of this humble art, or teach a man to become a shoemaker. A day or two in a shoemaker's shop will answer the end better than a whole folio of instruction, which only serves to oppress the learner with the weight of its pretended importance. We have lately seen a laborious work carried on at Paris with this only intent of teaching all the trades by description; however, the design at first bluish seems to be ill considered; and it is probable that very few advantages will be derived from so laborious an undertaking. With regard to the descriptions in natural history, these, without all question, under the direction of good sense, are necessary; but still they should be kept within proper bounds; and, where a thing may be much more easily shown than described, the exhibition should ever precede the account.

## CHAP. XV.

### OF QUADRUPEDS IN GENERAL COMPARED TO MAN.

Upon comparing the various animals of the globe with each other, we shall find that Quadrupeds demand the rank immediately next ourselves, and consequently come first in consideration. The similitude between the structure of their bodies and ours—those instincts which they enjoy in a superior degree to the rest—their constant services or unceasing hostilities—all render them the foremost objects of our curiosity, and the most interesting parts of Animated Nature. These, however, although now so completely subdued, very probably in the beginning were nearer upon an equality with us, and disputed the possession of the earth. Man, while yet savage himself, was but ill qualified to civilise the forest. While yet naked, unarmed, and without shelter, every wild beast was a formidable rival; and the destruction of such was the first employment of heroes. But when he began to multiply and arts to accumulate, he soon cleared the plains of the most noxious of these his rivals; a part was taken under his protection and care, while the rest found a precarious refuge in the burning desert or the howling wilderness.

From being rivals, quadrupeds have now become the assistants of man; upon them he devolves the most laborious employments, and finds in them patient and humble coadjutors—ready to obey, and content with the smallest kindness. It was not, however, without long and repeated efforts that the independent spirit of these animals was broken; for the savage freedom in wild animals is generally found to pass down through several generations before it is totally subdued. Those cats and dogs that are taken from a state of natural wildness in the forest transmit their fierceness to their young: and, however concealed in general, it breaks out upon several occasions. Thus the assiduity and application of man in bringing them up not only alters their dispositions but their forms; and the difference between animals in a state of nature and domestic tameness is so considerable, that Mr. Buffon has taken this as a principal distinction in classing them.

In taking a cursory view of the form of quadrupeds, we may easily perceive that of all the ranks of Animated Nature they bear the nearest resemblance to man. This similitude will be found more striking when erecting themselves on their hinder feet, when they are taught to walk forward in an upright posture. We then see that all their extremities in a manner correspond with ours, and present us with a rude imitation of our own. In some of the ape kind the resemblance is so striking, that anatomists are puzzled to find in what part of the human body man's superiority consists; and scarce any but the metaphysician can draw the line that ultimately divides them.

But if we compare their internal structure with our own the likeness will be found still to increase, and we shall perceive many advantages they enjoy common with us above the lower tribes of Nature. Like us, they are placed above the class of birds, by bringing forth their young alive; like us, they are placed above the class of fishes, by breathing through the lungs; like us, they are placed above the class of insects, by having red blood circulating through their veins; and, lastly, like us, they are different from almost all the other classes of Animated Nature, being either wholly or partly covered with hair. Thus nearly are we represented in point of conformation to the class of animals immediately below us; and this shows what little reason we have to be proud of our persons alone, to the perfection of which quadrupeds make such very near approaches.

The similitude of quadrupeds to man obtains also in the fixedness of their nature, and their being less apt to be changed by the influence of climate or food than the lower ranks of Nature. Birds are found very apt to alter both in colour and size; fishes, likewise, still more; insects may be quickly brought to change and adapt themselves to the climate; and if we descend to plants—which may be allowed to have a kind of living existence—their kinds may be surprisingly and readily altered, and taught to assume new forms. The figure of every animal may be considered as a kind of drapery, which it may be made to put on or off by human assiduity; in man the drapery is almost invariable; in quadrupeds it varies; and the variety may be made greater still as we descend to the inferior classes of animal existence.

Quadrupeds, although they are thus strongly marked, and in general divided from the various kinds around them, yet some of them are often of so equivocal a nature, that it is hard to tell whether they ought to be ranked in the quadruped class or degraded to those below them. If, for instance, we were to marshal the whole group of animals round man, placing the most perfect next him and those most equivocal near the classes they most approach, we should find it difficult, after the principals had taken their stations near him, where to place many that lie at the outskirts of this phalanx. The bat makes a near approach to the aerial tribe, and might by some be reckoned among the birds. The porcupine has not less pretensions to that class—being covered with quills, and showing that birds are not the only part of Nature that are furnished with such a defence. The armadilla might be referred to the tribe of insects, or snails—being like them covered with shells; the seal and the morse might be ranked among the fishes—like them being furnished with fins, and almost constantly residing in the same element. All these, the farther they recede from the human figure become less perfect, and may be considered as the lowest kinds of that class to which we have referred them.

But although the variety in quadrupeds is thus great, they all seem well adapted to the stations in which they are placed. There is scarce one of them, how rudely shaped soever, that is not formed to enjoy a state of happiness fitted to its nature. All its deformities are only relative to us, but all its enjoyments are peculiarly its own. We may superficially suppose the sloth (that takes up months in climbing a single tree) or the mole (whose eyes are too small for a distinct vision) are wretched and helpless creatures; but it is probable that their life, with respect to themselves, is a life of luxury; the most pleasing food is easily obtained; and as they are abridged in one pleasure it may be doubled in those which remain. Quadrupeds, and all the lower kinds of animals, have at worst but the torments of immediate evil to encounter—and this is but transient and accidental; man has two sources of calamity—that which he foresees as well as that which he feels; so that, if his reward were to be in this life alone, then, indeed, would he be of all beings the most wretched.

The heads of quadrupeds, though differing from each other, are in general adapted to their way of living. In some it is sharp—the better to fit the animal for turning up the earth in which its food lies; in some it is long—in order to give a greater room for the olfactory nerves, as in dogs, who are to hunt and find out their prey by the scent; in others it is short and thick, as in the lion, to increase the strength of the jaw, and to fit it the better for combat; in quadrupeds that feed upon grass, they are enabled to hold down their heads to the ground by a strong tendinous ligament which runs from the head to the middle of the back. This serves to raise the head, although it has been held to the ground for several hours, without any labour or any assistance from the muscles of the neck.

The teeth of animals are entirely fitted to the nature of their food. Those of such as live upon flesh differ in every respect from such as live upon vegetables. In the latter, they seem entirely made for gathering and bruising their simple food, being edged before and fitted for cutting, but broad towards the back of the jaw and fitted for pounding. In the carnivorous kinds, they are sharp before and fitted rather for holding than dividing. In the one, the teeth serve as grindstones—in the other, as weapons of defence; in both, however, the surface of those teeth which serve for grinding are unequal—the cavities and risings fitting those of the opposite so as to tally exactly when the jaws are brought together. These inequalities better serve for comminuting the food; but they become smooth with age—and for this reason old animals take a longer time to chew their food than such as are in the vigour of life.

Their legs are not better fitted than their teeth to their respective wants or enjoyments. In some they are made for strength only, and to support a vast unwieldy frame without much flexibility or beauty of proportion. Thus the legs of the elephant, the rhinoceros, and the sea-horse resemble pillars. Were they made smaller they would be unfit to support the body; were they endowed with greater flexibility or swiftness, that would be needless, as they do not pursue other animals for food; and, conscious of their own superior strength, there are none that they design to avoid. Deers, hares, and other creatures, that are to find safety only in flight, have their legs made entirely for speed; they are slender and nervous. Were it not for this advantage, every carnivorous animal would soon make them a prey, and their races would be entirely extinguished; but in the present state of nature the means of safety are rather superior to those of offence, and the pursuing animal must owe success only to patience, perseverance, and industry. The feet of some that live upon fish alone are made for swimming. The toes of these animals are joined together with membranes, being web-footed, like a goose or a duck, by which they swim with great rapidity. Those animals that lead a life of hostility, and live upon others, have their feet armed with sharp claws, which some can sheath and unsheath at will. Those, on the contrary, who lead peaceful lives, have generally hoofs, which serve some as weapons of defence; and which, in all, are better fitted for traversing extensive tracts of rugged country than the claw-foot of their pursuers.

The stomach is generally proportioned to the quality of the animal's food, or the ease with which it is obtained. In those that live upon flesh and such nourishing substances, it is small and glandular, affording such juices as are best adapted to digest its contents; their intestines, also, are short, and without fatness. On the contrary, such animals as feed entirely upon vegetables have the stomach very large; and those who chew the cud have no less than four stomachs, all which serve as so many laboratories to prepare and turn their coarse food into proper nourishment. In Africa, where the plants afford greater nourishment than in our temperate climates, several animals that with us have four stomachs

have there but two. However, in all animals the size of the intestines are proportioned to the nature of the food; where that is furnished in large quantities the stomach dilates to answer the increase. In domestic animals that are plentifully supplied it is large; in the wild animals that live precariously it is much more contracted, and the intestines are much shorter.

In this manner, all animals are fitted by nature to fill up some peculiar station. The greatest animals are made for an inoffensive life—to range the plains and the forest without injuring others—to live upon the productions of the earth, the grass of the field, or the tender branches of trees. These, secure in their own strength, neither fly from any other quadrupeds nor yet attack them: Nature to the greatest strength has added the most gentle and harmless dispositions; without this, those enormous creatures would be more than a match for all the rest of the creation—for what devastation might not ensue were the elephant, the rhinoceros, or the buffalo as fierce and mischievous as the tiger or the rat? In order to oppose these larger animals, and in some measure to prevent their exuberance, there is a species of the carnivorous kind, of inferior strength indeed, but of greater activity and cunning. The lion and the tiger generally watch for the larger kinds of prey, attack them at some disadvantage, and commonly jump upon them by surprise. None of the carnivorous kinds, except the dog alone, will make a voluntary attack but with the odds on their side. They are all cowards by nature, and usually catch their prey by a bound from some lurking place, seldom attempting to invade them openly; for the larger beasts are too powerful for them, and the smaller too swift.

A lion does not willingly attack a horse; and then only when compelled by the keenest hunger. The combats between a lion and a horse are frequent enough in Italy; where they are both enclosed in a kind of amphitheatre, fitted for that purpose. The lion always approaches wheeling about, while the horse presents his hinder parts to the enemy. The lion in this manner goes round and round, still narrowing his circle, till he comes to the proper distance to make his spring; just at the time the lion springs the horse lashes with both legs from behind, and in general the odds are in his favour—it more often happening that the lion is stunned and struck motionless by the blow than that he effects his jump between the horse's shoulders. If the lion is stunned and left sprawling, the horse escapes without attempting to improve his victory; but if the lion succeeds, he sticks to his prey, and tears the horse to pieces in a very short time.

But it is not among the larger animals of the forest alone that these hostilities are carried on; there is a minuter and a still more treacherous contest between the lower ranks of quadrupeds. The panther hunts for the sheep and the goat; the catamountain for the hare or the rabbit; and the wild cat for the squirrel or the mouse. In proportion as each carnivorous animal wants strength, it uses all the assistance of patience, assiduity, and cunning. However, the arts of these to pursue are not so great as the tricks of their prey to escape; so that the power of destruction in one class is inferior to the power of safety in the other. Were this otherwise, the forest would soon be dispeopled of the feebler races of animals; and beasts of prey themselves would want at one time that subsistence which they have lavishly destroyed at another.

Few wild animals seek their prey in the day-time; they are then generally deterred by their fears of man in the inhabited countries, and by the excessive heat of the sun in those extensive forests that lie towards the south, and in which they reign the undisputed tyrants. As soon as the morning, therefore, appears, the carnivorous animals retire to their dens; and the elephant, the horse, the deer, and all the hare kinds—those inoffensive

tenants of the plain—make their appearance. But again at nightfall the state of hostility begins; the whole forest then echoes to a variety of different howlings. Nothing can be more terrible than an African landscape at the close of evening; the deep-toned roarings of the lion—the thriller yellings of the tiger—the jackall, pursuing by the scent and barking like a dog—the hyena, with a note peculiarly solitary and dreadful; but above all, the hissing of the various kinds of serpents, that then begin their call, and, as I am assured, make a much louder symphony than the birds in our groves in a morning.

Beasts of prey seldom devour each other—nor can anything but the greatest degree of hunger induce them to it. What they chiefly seek after is the deer or the goat—those harmless creatures that seem to embellish Nature. These are either pursued or surprised, and afford the most agreeable repast to their destroyers. The most usual method with even the fiercest animals is to hide and crouch near some path frequented by their prey, or some water where cattle come to drink, when they seize them at once with a bound. The lion and the tiger leap twenty feet at a spring; and this, rather than their swiftness or strength, is what they have most to depend upon for a supply. There is scarce one of the deer or hare kind that is not very easily capable of escaping them by its swiftness; so that whenever any of these fall a prey it must be owing to their own inattention.

But there is another class of the carnivorous kind that hunt by the scent, and which it is much more difficult to escape. It is remarkable that all animals of this kind pursue in a pack, and encourage each other by their mutual cries. The jackall, the syagush, the wolf, and the dog are of this kind: they pursue with patience rather than swiftness; their prey flies at first, and leaves them for miles behind; but they keep on with a constant, steady pace, and excite each other by a general spirit of industry and emulation, till at last they share the common plunder. But it too often happens that the larger beasts of prey when they hear a cry of this kind begun pursue the pack, and when they have hunted down the animal come in and monopolize the spoil. This has given rise to the report of the jackall's being the lion's provider; when the reality is, that the jackall hunts for itself, and the lion is an unwelcome intruder upon the fruits of his toil.

Nevertheless, with all the powers which carnivorous animals are possessed of they generally lead a life of famine and fatigue. Their prey has such a variety of methods of escaping, that they sometimes continue without food for a fortnight together: but Nature has endowed them with a degree of patience equal to the severity of their state—so that as their subsistence is precarious their appetites are complying. They usually seize their prey with a roar either of seeming delight or, perhaps, to terrify it from resistance. They frequently devour it, bones and all, in the most ravenous manner; and then retire to their dens, continuing inactive till the calls of hunger again excite their courage and industry. But as all their methods of pursuit are counteracted by the arts of evasion, they often continue to range without success, supporting a state of famine for several days, nay, sometimes weeks, together. Of their prey, some find protection in holes, in which Nature has directed them to bury themselves; some find safety by swiftness, and such as are possessed of neither of these advantages generally herd together, and endeavour to repel invasion by united force. The very sheep, which to us seem so defenceless, are by no means so in a state of Nature; they are furnished with arms of defence and a very great degree of swiftness; but they are still further assisted by their spirit of mutual defence: the females fall into the centre; and the males, forming a ring round them, oppose their horns to the assailants. Some animals, that feed upon fruits which are to be found only at one time

of the year, fill their holes with several sorts of plants, which enable them to lie concealed during the hard frosts of the winter, contented with their prison, since it affords them plenty and protection. These holes are dug with so much art that there seems the design of an architect in the formation. There are usually two apertures, by one of which the little inhabitant can always escape when the enemy is in possession of the other. Many creatures are equally careful of avoiding their enemies, by placing a sentinel to warn them of the approach of danger. These generally perform this duty by turns; and they know how to punish such as have neglected their post, or have been unmindful of the common safety. Such are a part of the efforts that the weaker races of quadrupeds exert to avoid their invaders, and in general they are attended with success. The arts of instinct are most commonly found an overmatch for the invasions of instinct. Man is the only creature against whom all their little tricks cannot prevail. Wherever he has spread his dominion scarce any flight can save, or any retreat harbour; wherever he comes terror seems to follow, and all society ceases among the inferior tenants of the plain: their union against him can yield them no protection, and their cunning is but weakness. In their fellow brutes they have an enemy whom they can oppose with an equality of advantage; they can oppose fraud or swiftness to force, or numbers to invasion; but what can be done against such an enemy as man, who finds them out though unseen, and though remote destroys them? Wherever he comes all the contests among the meaner ranks seem to be at an end, or is carried only by surprise. Such as he has thought proper to protect have calmly submitted to his protection; such as he has found convenient to destroy carry on an unequal war, and their numbers are every day decreasing.

The wild animal is subject to few alterations, and in a state of savage nature continues for ages the same in size, shape, and colour. But it is otherwise when subdued and taken under the protection of man; its external form, and even its internal structure, are altered by human assiduity—and this is one of the first and greatest causes of the variety that we see among the several quadrupeds of the same species. Man appears to have changed the very nature of domestic animals by cultivation and care. A domestic animal is a slave that seems to have few other desires but such as man is willing to allow it. Humble, patient, resigned, and attentive, it fills up the duties of its station—ready for labour, and content with subsistence.

Almost all domestic animals seem to bear the marks of servitude strong upon them. All the varieties in their colour—all the fineness and length of their hair, together with the depending length of their ears, seem to have arisen from a long continuance of domestic slavery. What an immense variety is there to be found in the ordinary race of dogs and horses! the principal differences of which have been effected by the industry of man so adapting the food, the treatment, the labour, and the climate, that Nature seems almost to have forgotten her original design; and the tame animal no longer bears any resemblance to its ancestors in the woods around him.

In this manner, Nature is under a kind of constraint in those animals we have taught to live in a state of servitude near us. The savage animals preserve the marks of their first formation; their colours are generally the same; a rough dusky brown or a tawny seem almost their only varieties. But it is otherwise in the tame; their colours are various, and their forms different from each other. The nature of the climate, indeed, operates upon all, but more particularly on these. That nourishment which is prepared by the hand of man (most adapted to their appetites, but to suit his own convenience)—that climate, the rigours of which he can

soften—and that employment to which they are sometimes assigned to, produce a number of distinctions that are to be found among the savage animals. These at first were accidental, but in time became hereditary; and a new race of monsters are propagated, rather to answer to the purposes of human pleasure than their own convenience. In short, their very appetites may be changed; and those that feed only upon grass may be rendered carnivorous. I have seen a sheep that would eat flesh, and a horse that was fond of oysters.

But not their appetites or their figure alone, but their very dispositions and their natural sagacity, are altered by the vicinity of man. In those countries where men have seldom intruded, some animals have been found established in a kind of civil state of society. Remote from the tyranny of man, they seem to have a spirit of mutual benevolence and mutual friendship. The beavers in these distant solitudes are known to build like architects and rule like citizens. The habitations that these have been seen to erect exceed the houses of the human inhabitants of the same country, both in neatness and convenience. But as soon as man intrudes upon their society they seem impressed with the terrors of their inferior situation; their spirit of society ceases, the bond is dissolved, and every animal looks for safety in solitude, and there tries all its little industry to shift only for itself.

Next to human influence, the climate seems to have the strongest effect both upon the nature and form of quadrupeds. As in man, we have seen some alterations produced by the variety of his situation, so in the lower ranks that are more subject to variation the influence of climate is more readily perceived. As these are more nearly attached to the earth, and in a manner connected to the soil—as they have none of the arts of shielding off the inclemency of the weather or softening the rigours of the sun, they are consequently more changed by its variations. In general, it may be remarked that the colder the climate the larger and warmer is the fur of each animal—it being wisely provided by Nature that the inhabitant should be adapted to the rigours of its situation. Thus the fox and the wolf, which in temperate regions have short hair, have a fine long fur in the frozen regions near the pole. On the contrary, those dogs which with us have long hair, when taken to Guinea or Angola in a short time cast their thick covering and assume a lighter dress, one more adapted to the warmth of the country. The beaver and the ermine, which are found in the greatest plenty in the cold regions, are remarkable for the warmth and delicacy of their furs; while the elephant and the rhinoceros, which are natives of the line, have scarce any hair. Not but that human industry can in some measure co-operate with or repress the effects of climate in this particular. It is well known what alterations are produced by proper care in the sheep's fleece in different parts of our own country; and the same industry is pursued with a like success in Syria, where many of their animals are clothed with a long and beautiful hair, which they take care to improve, as they work it into that stuff called camblet—so well known in different parts of Europe.

The disposition of the animal seems also not less marked by the climate than the figure. The same causes that seem to have rendered the human inhabitants of the rigorous climates savage and ignorant have also operated upon their animals. Both at the line and the pole the wild quadrupeds are fierce and untameable. In these latitudes—their savage dispositions having not been quelled by any efforts from man, and being still farther stimulated by the severity of the weather—they continue fierce and untractable. Most of the attempts which have hitherto been made to tame the wild beasts brought home from the pole or the equator have proved ineffectual. They are gentle and harmless enough while young; but as they grow up they acquire their natural

ferocity, and snap at the hand that feeds them. It may indeed, in general be asserted, that in all countries where the men are most barbarous the beasts are most fierce and cruel: and this is but a natural consequence of the struggle between man and the more savage animals of the forest; for in proportion as he is weak and timid they must be bold and intrusive—in proportion as his dominion is but feebly supported their rapacity must be more obnoxious. In the extensive countries, therefore, lying round the pole or beneath the line, the quadrupeds are fierce and formidable. Africa has ever been remarked for the brutality of its men and the fierceness of its animals: its lions and its leopards are not less terrible than its crocodiles and its serpents; their dispositions seem entirely marked with the rigours of the climate; and, being bred in an extreme heat, they show a peculiar ferocity that neither the force of man can conquer nor his arts allay. However, it is happy for the wretched inhabitants of those climates that its most formidable animals are all solitary ones—that they have not learnt the art of uniting to oppress mankind; but each, depending upon its own strength, invades without any assistant.

The food, also, is another cause in the variety which we find among the quadrupeds of the same kind. Thus the beasts which feed in the valley are generally larger than those which glean a scanty subsistence on the mountain. Such as live in the warm climates, where the plants are much larger and more succulent than with us, are equally remarkable for their bulk. The ox fed in the plains of Hindostan is much larger than that which is more hardily maintained on the side of the Alps. The deserts of Africa, where the plants are extremely nourishing, produce the largest and fiercest animals; and, perhaps, for a contrary reason, America is found not to produce such large animals as are seen in the ancient continent. But, whatever be the reason, the fact is certain, that while America exceeds us in the size of its reptiles of all kinds, it is far inferior in its quadruped productions. Thus, for instance, the largest animal of that country is the tapir, which can by no means be compared to the elephant of Africa. Its beasts of prey, also, are divested of that strength and courage which is so dangerous in this part of the world. The American lion, tiger, and leopard—if such diminutive creatures deserve their names—are neither so fierce nor so valiant as those of Africa and Asia. The tiger of Bengal has been seen to measure twelve feet in length, without including the tail; whereas the American tiger seldom exceeds three. This difference obtains still more in the other animals of that country—so that some have been of opinion that all quadrupeds in Southern America are of a different species from those most resembling them in the old world; and that there are none which are common to both but such as have entered America by the north; and which, being able to bear the rigours of the frozen pole, have travelled from the ancient continent by that passage into the new. Thus the bear, the wolf, the elk, the stag, the fox, and the beaver, are known to the inhabitant as well of North America as of Russia; while most of the various kinds to the southward in both continents bear no resemblance to each other. Upon the whole, such as peculiarly belong to the new continent are without any marks of the quadruped perfection. They are almost wholly destitute of the power of defence; they have neither formidable teeth, horns, nor tail; their figure is awkward, and their limbs ill-proportioned. Some among them, such as the ant-bear and the sloth, appear so miserably formed as scarce to have the power of moving and eating. They seemingly drag out a miserable and languid existence in the most desert solitude, and would quickly have been destroyed in a country where there were inhabitants or powerful beasts to oppose them.

But if the quadrupeds of the new continent be less

they are found in much greater abundance; for it is a rule that obtains through Nature that the smallest animals multiply the fastest. The goat imported from Europe to South America soon begins to degenerate; but as it grows less it becomes more prolific; and, instead of one kid at a time, or two at the most, it generally produces five, and sometimes more. What there is in the food or the climate that produces this change we have not been able to learn; we might be apt to ascribe it to the heat, but on the African coast, where it is still hotter, this rule does not obtain; for the goat, instead of degenerating there, seems rather to improve.

However, the rule is general among all quadrupeds, that those which are large and formidable produce but a few at a time; while such as are mean and contemptible are extremely prolific. The lion or tiger have seldom above two cubs at a litter; while the cat, which is of a similar nature, is usually seen to have five or six. In this manner the lower tribes become extremely numerous, and but for this surprising fecundity, from their natural weakness, they would quickly be extirpated. The breed of mice, for instance, would have long since been blotted from the earth, were the mouse as slow in production as the elephant. But it has been wisely provided that such animals as can make but little resistance should at least have a means of repairing the destruction which they must often suffer by their quick reproduction—that they should increase even among enemies, and multiply under the hand of the destroyer. On the other hand, it has as wisely been ordered by Providence that the larger kinds should produce but slowly; otherwise, as they require proportional supplies from Nature, they would quickly consume their own store; and, of consequence, many of them would soon perish through want—so that life would thus be given without the necessary means of subsistence. In a word, Providence has most wisely balanced the strength of the great against the weakness of the little. Since it was necessary that some should be great and others mean—since it was expedient that some should live upon others, it has assisted the weakness of one by granting it fruitfulness, and diminished the number of the other by infecundity.

In consequence of this provision the larger creatures, which bring forth few at a time, seldom begin to degenerate till they have nearly acquired their full growth. On the contrary, those which bring many reproduce before they have arrived at half their natural size. Thus the horse and the bull are nearly at their best before they begin to breed; the hog and the rabbit scarce leave the teat before they become parents in turn. Almost all animals likewise continue the time of their pregnancy in proportion to their size. The mare continues eleven months with foal, the cow nine, the wolf five, and the bitch nine weeks. In all the intermediate litters are the most fruitful—the first and the last generally producing the fewest in number and the worst of the kind.

Whatever be the natural disposition of animals at other times, they all acquire new courage when they consider themselves as defending their young. No terrors can then drive them from the part of duty; the mildest begin to exert their little force, and resist the most formidable enemy. Where resistance is hopeless, they then incur every danger in order to rescue their young by flight, and retard their own expedition by providing for their little ones. When the female opossum, an animal of America, is pursued, she instantly takes her young into a false belly with which Nature has supplied her, and carries them off or dies in the endeavour. I have been lately assured of a she-fox which, when hunted, took her cub in her mouth, and run for several miles without quitting it, until at last she was forced to leave it behind upon the approach of a mastiff, as she ran through a farmer's yard. But if at this period the mildest animals acquire new fierceness, how formidable must those be that subsist by rapine! At such times

no obstacles can stop their ravage, nor no threats can terrify; the lioness then seems more hardy than even the lion himself. She attacks men and beasts indiscriminately, and carries all she can overcome reeking to her cubs, whom she thus early accustoms to slaughter. Milk in the carnivorous animals is much more sparing than in others; and it may be for this reason that all such carry home their prey alive, that, in feeding their young, its blood may supply the deficiencies of Nature, and serve instead of that milk with which they are so sparingly supplied.

Nature, that has thus given them courage to defend their young, has given them instinct to choose the proper times of copulation, so as to bring forth when the provision suited to each kind is to be found in the greatest plenty. The wolf, for instance, couples in December; so that, the time of pregnancy continuing five months, it may have its young in April. The mare, who goes eleven months, admits the horse in summer in order to foal about the beginning of May. On the contrary, those animals which lay up provisions for the winter, such as the beaver and the marmotte, couple in the latter end of autumn, so as to have their young about January, against which season they have provided a very comfortable store. These seasons for coupling, however, among some of the domestic kinds are generally in consequence of the quantity of provisions with which they are at any time supplied. Thus we may, by feeding any of these animals and keeping off the rigour of the climate, make them breed whenever we please. In this manner those contrive who produce lambs all the year round.

The choice of situation in bringing forth is also very remarkable. In most of the rapacious kinds the female takes the utmost precautions to hide the place of her retreat from the male, who otherwise, when pressed by hunger, would be apt to devour her cubs. She seldom, therefore, strays far from her den, and never approaches while he is in view, nor visits him again till her young are capable of providing for themselves. Such animals as are of tender constitutions take the utmost care to provide a place of warmth as well as safety for their young; the rapacious kinds bring forth in the thickest woods; those that chew the cud, with the various tribes of the vermin kind, choose some hiding-place in the neighbourhood of man. Some dig holes in the ground, some choose the hollow of a tree, and all the amphibious kinds bring up their young near the water, and accustom them betimes to their proper element.

Thus Nature seems kindly careful for the protection of the meanest of her creatures: but there is one class of quadrupeds that seems entirely left to chance, that no parent stands forth to protect, nor no instructor leads to teach the arts of subsistence. These are the quadrupeds that are brought forth from the egg, such as the lizard, the tortoise, and the crocodile. The fecundity of all other animals compared with these is sterility itself. These bring forth above two hundred at a time; but as the offspring is more numerous the parental care is less exerted. Thus the numerous broods of eggs are, without farther solicitude, buried in the warm sands of the shore, and the heat of the sun alone is left to bring them to perfection. To this perfection they arrive almost as soon as disengaged from the shell. Most of them, without any other guide than instinct, immediately make to the water. In their passage thither they have numberless enemies to fear. The birds of prey that haunt the shore, the beasts that accidentally come that way, and even the animals that give them birth, are known, with a strange rapacity, to thin their numbers as well as the rest.

But it is kindly ordered by Providence that those animals which are mostly obnoxious should thus have many destroyers; were it not for this, by their extreme fecundity they would soon over-run the earth, and cumber all our plains with deformity.

## PART III.

### ANIMALS OF THE HORSE KIND.

#### BOOK I.—CHAP. I.

##### OF THE HORSE.

Animals of the horse kind deserve a place next to man in a History of Nature. Their activity, their strength, their usefulness, and their beauty, all contribute to render them the principal objects of our curiosity and care—a race of creatures in whose welfare we are interested next to our own.

Of all the quadruped animals the horse seems the most beautiful; the noble largeness of his form, the glossy smoothness of his skin, the graceful ease of his motions, and the exact symmetry of his shape, have taught us to regard him as the first and the most perfectly formed; and yet, what is extraordinary enough, if we examine him internally, his structure will be found the most different from that of man of all other quadrupeds whatsoever. As the ape approaches us the nearest in internal conformation, so the horse is the most remote—a striking proof that there may be oppositions of beauty, and that all grace is not to be referred to one standard.

To have an idea of this noble animal in his native simplicity, we are not to look for him in the pastures or the stables, to which he has been consigned by man, but in those wild and extensive plains where he has been originally produced—where he ranges without control, and riots in all the variety of luxurious Nature. In this state of happy independence he disdains the assistance of man, which only tends to servitude. In those boundless tracts, whether of Africa or New Spain, where he runs at liberty, he seems no way incommoded with the inconveniences to which he is subject in Europe. The continual verdure of the fields supplies his wants; and the climate, that never knows a winter, suits his constitution, which naturally seems adapted to heat. His enemies of the forest are but few—for none but greater kinds will venture to attack him; any one of these he is singly able to overcome; while, at the same time, he is content to find safety in society; for the wild horses of those countries always herd together.

In these countries, therefore, the horses are often seen feeding in droves of five or six hundred. As they do not carry on war against any other race of animals, they are satisfied to remain entirely upon the defensive. The pastures on which they live satisfy all their appetites, and all other precautions are purely for their security in case of a surprise. As they are never attacked at a disadvantage, whenever they sleep in the forests they have always one among their number that stands in sentinel, to give notice of any approaching danger; and this office they take by turns. If a man approaches them while they are feeding by day their sentinel walks

up boldly near him, as if to examine his strength, or to intimidate him from proceeding; but if the man approaches within pistol-shot, the sentinel then thinks it high time to alarm his fellows; this he does by a loud kind of snorting, upon which they all take the signal, and fly off with the speed of the wind—their faithful sentinel bringing up the rear.

It is not easy to say from what country the horse came originally. It should seem that the colder climates do not agree with his constitution; for although he is found almost in them all, yet his form is altered there, and he is found at once diminutive and ill shaped. We have the testimony of the ancients that there were wild horses once in Europe; at present, however, they are totally brought under subjection; and even those which are found in America are of a Spanish breed, which, being sent thither upon its first discovery, have since become wild, and have spread over all the south of that vast continent almost to the straits of Magellan. These in general are a small breed, of about fourteen hands high. They have thick jaws and clumsy joints; their ears and neck, also, are long; they are easily tamed—for the horse by nature is a gentle, complying creature, and resists rather from fear than obstinacy. They are caught by a kind of noose, and then held fast by the legs and tied to a tree, where they are left for two days without food or drink. By that time they begin to grow manageable; and in some weeks they become as tame as if they had never been in a state of wildness. If by any accident they are once more set at liberty they never become wild again, but know their masters, and come to their call. Some of the buccaneers have often been agreeably surprised, after a long absence, to see their faithful horses once more present themselves with their usual assiduity, and come up with a fond submission to receive the rein.

These American horses, however, cannot properly be ranked among the wild races, since they were originally bred from such as were tame. It is not in the new, but in the old world that we are to look for this animal in a true state of nature—in the extensive deserts of Africa, in Arabia, and those wide-spread countries that separate Tartary from the more southern nations. Vast droves of these animals are seen wild among the Tartars: they are of a small breed, extremely swift, and very readily evade their pursuers. As they go together, they will not admit of any strange animals among them, though even of their own kind. Whenever they find a tame horse attempting to associate with them they instantly gather round him, and soon oblige him to seek safety by flight. There are vast numbers also of wild horses to the north of China, but they are of a weak, timid breed—small of stature and useless in war.

At the Cape of Good Hope there are numbers of horses

in a state of nature, but they are small, vicious, and untameable. They are found wild, also, in several other parts of Africa; but the wretched inhabitants of that country either want the art to tame them or seem ignorant of their uses. It is common with the Negroes, who are carried over from thence to America, when they first see a horse to testify both terror and surprise. These poor men seem not to have any knowledge of such a creature; and, though the horse is probably a native of their own country, they have let all the rest of mankind enjoy the benefit of his services without turning them to any advantage at home. In some parts of Africa, therefore, where the horse runs wild, the natives seem to consider it rather in the light of a dainty food than an useful creature capable of assisting them either in war or labour: riding seems a refinement that the natives of Angola or Caffraria have not as yet acquired; and when they catch a horse it is with an intent to eat him.

But of all countries in the world where the horse runs wild Arabia produces the most beautiful breed—the most generous, swift, and persevering. They are found, though not in great numbers, in the deserts of that country; and the natives use every stratagem to take them. Although they are active and beautiful, yet they are not so large as those that are bred up tame; they are of a brown colour, their mane and tail very short, and the hair black and tufted. Their swiftness is incredible; the attempt to pursue them in the usual manner of the chase with dogs would be entirely fruitless. Such is the rapidity of their flight that they are instantly out of view, and the dogs themselves give up the vain pursuit. The only method, therefore, of taking them is by traps hidden in the sand, which, entangling their feet, the hunter at length comes up, and either kills them or carries them home alive. If the horse be young he is considered among the Arabians as a great delicacy, and they feast upon him while any part is found remaining; but if, from his shape or vigour, he promises to be serviceable in his more noble capacity, they take the usual methods of taming him by fatigue and hunger, and he soon becomes an useful domestic animal.

The usual manner of trying their swiftness is by hunting the ostrich: the horse is the only animal whose speed is comparable to that of this creature, which is found in the sandy plains, with which those countries abound. The instant the ostrich perceives itself aimed at it makes to the mountains, while the horseman pursues with all the swiftness possible, and endeavours to cut off its retreat. The chase then continues along the plain, while the ostrich makes use of both legs and wings to assist its motion. However, a horse of the first speed is able to out-run it; so that the poor animal is then obliged to have recourse to art to elude the hunter, by frequently turning: at length, finding all escape hopeless, it hides its head wherever it can, and suffers itself tamely to be taken. If the horse in a trial of this kind shows great speed and is not readily tired, his price becomes proportionably great, and there are some horses valued at a thousand ducats.

But the horses thus caught, or trained in this manner, at present are but very few; the value of Arabian horses over all the world has in a great measure thinned the deserts of the wild breed; and there are few to be found in those countries except such as are tame. The Arabians, as we are told by historians, first began the management of horses in the time of Sheque Ismael. Before that they wandered wild along the face of the country, neglected and useless; but the natives then first began to tame their fierceness and to improve their beauty; so that at present they possess a race of the most beautiful horses in the world, with which they drive a trade, and furnish the stables of princes at immense prices.

There is scarce an Arabian, how poor soever, but is provided with his horse. They in general make use of

mares in their ordinary excursions—experience having taught them that they support fatigue, thirst, and hunger better than the horses are found to do. They are also less vicious, of a gentler nature, and are not so apt to neigh. They are more harmless, also, among themselves—not so apt to kick or hurt each other, but remain whole days together without the least mischief. The Turks, on the contrary, are not partial to mares; and the Arabians sell them such horses as they do not choose to keep for stallions at home. They preserve the pedigree of their horses with great care, and for several ages back. They know their alliances and all their genealogy; they distinguish the races by different names, and divide them into three classes. The first is that of the nobles, the ancient breed, and unadulterated on either side; the second is that of the horses of the ancient race, but adulterated; and the third is that of the common and inferior kind. The last they sell at a low price; but those of the first class, and even of the second (amongst which are found horses of equal value to the former), are sold extremely dear. They know by long experience the race of a horse by his appearance; they can tell the name, the surname, the colour, and the marks properly belonging to each. When they are not possessed of stallions of the noble race themselves for their mares they borrow from their neighbours, paying a reasonable price, as with us, and receive a written attestation of the whole. In this attestation is contained the name of the horse as well as the mare, and their respective genealogies. When the mare has produced her foal new witnesses are called, and a new attestation signed, in which are described the marks of the foal, and the day noted when it was brought forth. These attestations increase the value of a horse, and they are given to the person who buys him. The most ordinary mare of this race sells for five hundred crowns; there are many that sell for a thousand, and some of the very finest kinds for fourteen or fifteen hundred pounds. As the Arabians have no other house but a tent to live in, this also serves them for a stable—so that the mare, the foal, the husband, the wife, and the children, lie all together indiscriminately: the little children are often seen upon the body or neck of the mare, while these continue indolgent and harmless, permitting them thus to play with and caress them without any injury. The Arabians never beat their horses: they treat them gently; they speak to them, and seem to hold a discourse; they use them as friends; they never attempt to increase their speed by the whip, nor spur them but in cases of necessity. However, when this happens, they set off with amazing swiftness: they leap over obstacles with as much agility as a buck; and if the rider happens to fall, they are so manageable that they stand still in the midst of their most rapid career. The Arabian horses are of a middle size, easy in their motions, and rather inclined to leanness than fat. They are regularly dressed every morning and evening, and with such care that the smallest roughness is not left upon their skins. They wash their legs, the mane, and the tail, which they never cut, and which they seldom comb, lest they should thin the hair. They give them nothing to eat during the day; they only give them to drink once or twice; and at sunset they hang a bag to their heads, in which there is about half a bushel of clean barley. They continue eating the whole night, and the bag is again taken away the next morning. They are turned out to pasture in the beginning of March, when the grass is pretty high, and at which time the mares are given to the stallion. When the spring is past they take them again from pasture, and they get neither grass nor hay during the rest of the year; barley is their only food, except now and then a little straw. The mane of the foal is always clipped when about a year or eighteen months old, in order to make it stronger and thicker. They begin to break them at two years old, or two years and a half at

farthest; they never saddle or bridle them till at that age, and then they are always kept ready saddled at the door of the tent from morning till sunset, in order to be prepared against any surprise. They at present seem sensible of the great advantage their horses are to the country; there is a law, therefore, that prohibits the exportation of the mares, and such stallions as are brought into England are generally purchased on the Eastern shores of Africa, and come round to us by the Cape of Good Hope. They are in general less in stature than our own, being not above fourteen or fourteen hands and a half high; their motions are much more graceful and swifter than that of our own horses; but nevertheless their speed is far from being equal; they run higher from the ground; their stroke is not so long and close; and they are far inferior in bottom. Still, however, they must be considered as the first and finest breed in the world, and that from which all others have derived their principal qualifications. It is even probable that Arabia is the original country of horses; since there, instead of crossing the breed, they take every precaution to keep it entire. In other countries they must continually change the races, or their horses would soon degenerate; but there the same blood has passed down through a long succession, without any diminution either of force or beauty.

The race of Arabian horses has spread itself into Barbary, among the Moors, and has even extended across that extensive continent to the western shores of Africa. Among the Negroes of Gambia and Senegal the chiefs of the country are possessed of horses which, though little, are very beautiful and extremely manageable. Instead of barley, they are fed in those countries with maize, bruised and reduced into meal, and mixed up with milk when they design to fatten them. These are considered as next to the Arabian horses both for swiftness and beauty; but they are rather still smaller than the former. The Italians have a peculiar sport, in which horses of this breed run against each other. They have no riders, but saddles so formed as to flap against the horses' sides as they move, and thus to spur them forward. They are set to run in a kind of railed walk, about a mile long, out of which they never attempt to escape; but, when they once set forward, they never stop, although the walk from one end to the other is covered with a crowd of spectators, which opens and gives way as the horses approach. Our horses would scarcely in this manner face a crowd, and continue their speed without a rider through the midst of a multitude; and, indeed, it is a little surprising how in such a place the horses find their own way. However, what our English horses may want in sagacity they make up by their swiftness; and it has been found upon computation that their speed is nearly one-fourth greater, even carrying a rider, than that of the swiftest Barb without one.

The Arabian breed has been diffused into Egypt as well as Barbary, and into Persia also—where, as we are told by Marcus Paulus, there are studs of ten thousand white mares altogether, very fleet, and with the hoof so hard that shoeing is unnecessary. In these countries they in general give their horses the same treatment that they give in Arabia, except that they litter them upon a bed of their own dung, dried in the sun, and then reduced to powder. When this, which is spread under the horse about five inches thick, is moistened, they dry it again, and spread it as before. The horses of these countries a good deal resemble each other. They are usually of a slender make; their legs fine, bony, and far apart; a thin mane and fine crest; a beautiful head; the ears small and well pointed; the shoulder thin; the side rounded, without any unsightly prominence; the croup is a little of the longest, and the tail is generally set high. The race of horses, however, is much degenerated in Numidia—the natives having been discouraged from keeping up the breed by the Turks, who seize upon all

the good horses, without paying the owners the smallest gratuity for their care in bringing them up. The Tingitani and Egyptians have now, therefore, the disadvantage of rearing the finest horses, both for size and beauty. The smallest of these last are usually sixteen hands high; and all of them shaped, as they express it, with the elegance of an antelope.

Next to the Barb, travellers generally rank the Spanish genetie. These horses, like the former, are little, but extremely swift and beautiful. The head is something of the largest; the mane thick; the ears long, but well pointed; the eyes filled with fire; the shoulder thickish, and the breast full and large; the croup round and large; the legs beautiful, and without hair; the pastern a little of the longest, as in the Barb, and the hoof rather too high. Nevertheless, they move with great ease, and carry themselves extremely well. Their most usual colour is black, or a dark bay. They seldom or never have white legs or white snip. The Spaniards, who have a groundless aversion to these marks, never breed from such as have them. They are all branded on the buttock with the owner's name; and those of the province of Andalusia pass for the best. These are said to possess courage, obedience, grace, and spirit, in a greater degree than even the Barb; and for this reason they have been preferred as war-horses to those of any other country.

The Italian horses were once more beautiful than they are at present, for they have greatly neglected the breed. Nevertheless, there are still found some beautiful horses among them, particularly among the Neapolitans, who chiefly use them for the draught. In general, they have large heads and thick necks. They are also restive, and consequently unmanageable. These faults, however, are recompensed by the largeness of their size, by their spirit, and the beauty of their motion. They are excellent for show, and have a peculiar aptitude to prance.

The Danish horses are of such an excellent size and so strong a make, that they are preferred to all others for the draught. There are some of them perfectly well shaped; but this is but seldom seen, for in general they are found to have a thick neck, heavy shoulders, long and hollow back, and a narrow croup: however, they all move well, and are found excellent both for parade and war. They are of all colours, and often of whimsical ones, some being streaked like the tiger or mottled like the leopard.

The German horses are originally from Arabian and Barbary stocks; nevertheless, they appear to be small and ill shaped: it is said, also, that they are weak and washy, with tender hoofs. The Hungarian horses, on the other hand, are excellent for the draught as well as the saddle. The Hussars, who use them in war, usually slit their nostrils; which is done, as it is said, to prevent their neighing, but, perhaps, without any real foundation.

The Dutch breed is good for the draught, and is generally used for that purpose over Europe: the best come from the province of Friesland. The Flanders horses are much inferior to the former; they have most commonly large heads, flat feet, and swollen legs—which are an essential blemish in horses of this kind.

The French horses are of various kinds; but they have few that are good. The best horses of that country come from Limosin; they have a strong resemblance to the Barb, and like them are excellent for the chase; but they are slow in coming to perfection: they are to be carefully treated while young, and must not be backed till they are eight years old. Normandy furnishes the next best, which, though not so good for the chase, are yet better for war. In general, the French horses have the fault of being heavy shouldered, which is opposite to the fault of the Barb, the latter being too thin in the shoulder, and is consequently apt to be shoulder-slip.

Having mentioned the horses most usually known in

Europe, we pass on to those of more distant countries, of which we can only judge by report. We mentioned the wild horses of America. Such as are tame, if we may credit the latest reports, are admirable. Great numbers of these are bred up to the chase, and are chiefly kept for this purpose, particularly at Quito. The hunters, as Ulloa informs us, are divided into two classes—one part on foot, the other on horseback; the business of the footmen is to rouse the deer, and that of the horsemen to hunt it down. They all at break of day repair to the place appointed, which is generally on the summit of a hill, with every man his greyhound. The horsemen place themselves on the highest peaks, whilst those on foot range the precipices, making a hideous noise to start the deer. Thus the company extend themselves three or four leagues or more, according to their numbers. On starting any game, the horse which first perceives it starts off, and the rider, being unable to guide or stop him, pursues the chase, sometimes down such a steep slope, that a man on foot with the greatest care could hardly keep his legs; from thence he flies up a dangerous ascent, or along the side of a mountain—so that a person not used to this exercise would think it much safer to throw himself out of the saddle than to commit his life to the precipitate ardour of his horse. The other horses which join in the chase do not wait for their riders to animate them; they set forward immediately upon seeing another at full speed; and it becomes prudence in the rider to give them their way, and at the same time to let them feel the spur, to carry him over the precipices. These horses are backed and exercised to this method of hunting; and their usual pace is trotting.

There are said to be very good horses in the islands of the Archipelago. Those of Crete were in great reputation among the ancients for their swiftness and force; however, at present they are but little used, even in the country itself, because of the unevenness of the ground, which is there very rocky and mountainous. The original horses of Morocco are much smaller than the Arabian breed; nevertheless they are exceedingly swift and vigorous. In Turkey there are to be found horses of almost all races—Arabians, Tartars, Hungarians, and those natural to the place. The latter are beautiful and elegant; they have a great deal of fire, swiftness, and management; but they are not able to support any fatigue. They eat little; they are easily heated; and they have skins so sensitive that they can scarce bear the rubbing of the stirrup. The Persian horses are in general the most beautiful and valuable of all the east. The pastures in the plains of Media, Persepolis, Ardebil, and Derbent are excellent for the purpose of rearing them; and there were bred in those places vast numbers by order of the government of Persia, while that country was under any government. Pietro della Valle prefers the horses of Persia to those of Italy, and says that they are in general of a middle size; and although some are found even of the smallest stature, yet that does not impair their beauty or their strength. In some places they are found of a good size, as large as the English saddle-horses are generally found to be: they have all thin heads, fine crest, narrow breast, small ears well placed, the legs fine, the hoof hard, and the croup beautiful; they are docile, spirited, nimble, hardy, courageous, and capable of supporting extraordinary fatigue; they run very swiftly without being easily distressed; they are strong and easy, being only supplied with barley and chopped straw; they are put to grass only for six weeks in the spring; they have always the tail at full length, and there is no such thing as geldings among the number; they are defended from the air, as in England, by body-clothes; they attend them with the most punctual exactness; and they are generally ridden in a snaffle, without spurs. Great numbers of these are every year transported into Turkey, but chiefly into the East Indies.

All travellers, however, agree that they are not to be compared to the Arabian horses either for courage, force, or beauty; and that the latter are eagerly sought even in Persia.

The horses of India are of a very indifferent kind, being weak and washy. Those which are used by the grandees of the country come from Persia and Arabia; they are fed with a small quantity of hay during the day, and at night they have boiled peas, mixed with sugar and butter, instead of oats or barley: this nourishment supports them and gives them strength, otherwise they would sink and degenerate. Those naturally belonging to the country are very small and vicious. Some are so very little, that Tavernier reports that the young Mogul prince, at the age of seven or eight, rode one of these little horses that was not much larger than a greyhound: and it is not long since one of these was brought over into this country, as a present to the Queen, that measured no more than nine hands high, and is not much larger than a common mastiff. It would seem that climates excessively hot are unfavourable to this animal. In this manner, the horses of the Gold-coast and of Guinea are extremely little, but very manageable. It is a common exercise with the grandees of that country, who are excellent horsemen, to dart out their lances before them upon full gallop, and to catch them again before they come to the ground. They have a sport, also, on horseback that requires great dexterity in the rider, and a great share of activity in the horse: they strike off a ball with a battledore while they are upon full gallop, and, pursuing it, strike it again before it comes to the ground; and this they continue for a mile together, striking sometimes to the right and sometimes to the left with amazing speed and agility.

The horses of China are as indifferent as those of India: they are weak, little, ill-shaped, and cowardly. Those of Corea are not above three feet high: almost all the breed there are made geldings, and are so timorous that they can be rendered no way serviceable in war; so that it may be said that the Tartar horses were properly the conquerors of China. These, indeed, are very serviceable in war; and although but of a middle size, yet they are surprisingly patient, vigorous, swift, and bold; their hoofs are extremely hard, though rather too narrow, their heads are fine, but rather too little; the neck is long and stiff; the legs of the longest; and yet, with all these faults, they are found to be an excellent breed. The Tartars live with their horses pretty much in the same manner as the Arabians do; they begin to back them at the age of seven or eight months, placing their children upon them, who manage them even at that early age. By these means they break them by little and little, till at last, about the age of six or seven years, they are capable of enduring amazing hardships. Thus they have been known to march two or three days without once stopping; to continue five or six without eating anything except a handful of grass every eight hours; and, besides, to remain without drinking for four and twenty hours. These horses, which are so vigorous in their own country, lose all their strength when they are brought into China or the Indies; but they thrive pretty well in Persia and Turkey. The race of little Tartars towards the north have also a breed of little horses, which they set such a value upon that it is forbidden to sell them to strangers: these horses have the very same qualities with those of the larger kind, which they probably derive from a similar treatment. There are also very fine horses in Circassia and Mingrelia. There are some greatly esteemed in the Ukraine, in Wallachia, Poland, and Sweden; but we have no particular accounts of their excellencies or defects.

If we consult the ancients on the nature and qualities of the horses of different countries, we learn that the Grecian horses, and particularly those of Thessaly, had the reputation of being excellent for war; that those of

Achaia were the largest that were known; that the most beautiful came from Egypt, which bred great numbers; that the horses of Æthiopia were not in esteem, from the heat of the country; that Arabia and Africa furnished very beautiful horses, and suitable for the course; that those of Italy, and particularly of Apulia, were very good; that in Sicily, Capadocia, Syria, Armenia, Media, and Persia there were excellent horses, equally esteemed for their speed and vigour; that those of Sardinia and Corsica, though small, were spirited and courageous; that those of Spain resembled the Parthian horses in being well adapted for war; that in Walachia and Transylvania there were horses with bushy tails, and manes hanging down to the ground, which, nevertheless, were extremely swift and active; that the Danish horses were good leapers; those of Scandinavia, though little, were well shaped, and possessed of great agility; that the Flanders breed was strong; that the Gaulish horses were good for carrying burthens; that the German breeds were so bad, so diminutive, and ill shaped, that no use could be made of them; that the Swiss and Hungarian horses were good; and, lastly, that those of India were very diminutive and feeble.

Such are the different accounts we have of the various races of horses in various parts of the world. I have hitherto omitted making mention of one particular breed, more excellent than any that either the ancients or the moderns have produced—and that is our own. It is not without great assiduity and unceasing application that the English horses are now become superior to those of any other part of the world for size, strength, swiftness, and beauty. It was not without great attention and repeated trials of all the best horses in different parts of the world that we have been thus successful in improving the breed of this animal; so that the English horses are now capable of performing what no others could ever attain to. By a judicious mixture of the several kinds, by the happy difference of our soils, and by our superior skill in management, we have brought this animal to its highest perfection. An English horse, therefore, is known to excel the Arabian in size and swiftness, to be more durable than the Barb, and more hardy than the Persian. An ordinary racer is known to go at the rate of a mile in two minutes; and we have one instance in the admirable Childers of still greater rapidity. He has been frequently known to move above eighty-two feet and a half in a second, or almost a mile in a minute; he has also run round the course at Newmarket (which is very little less than four miles) in six minutes and forty seconds. But what is surprising, few horses have been since found to equal him; and those of his breed have been remarkably deficient.

However this be, no horses can in any way equal our own, either in point of swiftness or strength; and these are the qualifications our horsemen seem chiefly to value. For this reason, when the French or other foreigners describe our breed, they all mention as a fault the awkward and ungainly motion of our horses; they allow them to be very good indeed, but they will not grant them an easy or an elegant carriage. But these writers do not consider that this seeming want of grace is entirely the result of our manner of breaking them. We consult only speed and despatch in this animal's motions; the French and other nations are more anxious for parade and spirit. For this reason we always throw our horses forward, while they put them upon their haunches; we give them an easy swift gait for going, which covers a great deal of ground; they, on the contrary, throw them back—giving them a more showy appearance, certainly, but one infinitely less useful. The fault of our manner of breaking is, that the horse is sometimes apt to fall forward; the French managed horse never falls before, but more usually on one side; and for this reason the rider wears stiff boots to guard his legs against such accidents. However, it would be

an easy matter to give our horses all the grace which foreigners are so fond of; but it would undoubtedly take from their swiftness and durability.

But in what degree of contempt soever foreigners might formerly have held our horses, they have for some time perceived their error, and our English hunters are considered as the noblest and the most useful horses in the world. Our geldings are accordingly sent over to the continent in great numbers, and sell at very great prices; as for our mares and stallions, there is a law prohibiting their exportation; and one similar to this is said to have obtained as early as the time of Athelstan, who prohibited their exportation except where designed as presents.

Roger de Belegme, created Earl of Shrewsbury by William the Conqueror, is the first who is recorded to have made attempts towards improving our native breed. He introduced Spanish stallions into his estate at Powisland, in Wales, from which that part of the country was for many ages after famous for a swift and generous race of horses. At that time, however, strength and swiftness were more regarded than beauty—the horse's shape in time of action being entirely hidden by a coat of armour, which the knights then usually put upon them either by way of ornament or defence.

The number of our horses in London alone in the time of King Stephen is said to have amounted to twenty thousand. Long after, however, in the time of Queen Elizabeth, the whole kingdom could not supply two thousand horses to form our cavalry. At present the former number seems revived; so that in the late war we furnished out above thirteen thousand horsemen; and we could, if hard pressed, supply above four times that number. How far this great increase of horses among us may be beneficial or otherwise is not the proper business of the present page to discuss; but certain it is, that where horses increase in too great a degree men must diminish proportionably—as that food which goes to supply the one might easily be converted into nourishment to serve the other. But it may be speculating too remotely to argue for the diminution of their numbers upon this principle—since every manufacture we export into other countries takes up room, and may have occupied that place which, in a state of greater simplicity, might have given birth and subsistence to mankind and have added to population.

Be this as it will, as we have been at such expense and trouble to procure an excellent breed of horses, it is not now to be expected that we should decline the advantages arising from it just when in our possession. It may therefore be the most prudent measure in our legislature to encourage the breed as an useful branch of commerce, and a natural defence to the country. But how far this end is answered by the breeding of racers is what most persons versed in this subject are very apt to question. They assert that the race-horse, as the breed has been for a long time refined, is unfit for any other service than that of the course—being too slight either for the road, the chase, or the combat, and his joints so delicately united as to render him subject to the smallest accident. They therefore conclude that less encouragement given to racing would be a means to turn us from breeding rather for swiftness than strength; and that we should thus be again famous for our strong hunters—which they affirm are wearing out from among us.

How far this may be the fact I will not take upon myself to determine, being but little versed in a subject that does not properly come within the compass of the present work. Instead, therefore, of further expatiating on this well-known animal's qualifications, upon which many volumes might easily be written, I will content myself with mentioning the description of Camerarius, in which he professes to unite all the perfections which a horse ought to be possessed of. "It must," he says,

"have three parts like those of a woman—the breast must be broad, the hips round, and the mane long; it must in three things resemble a lion—its countenance must be fierce, its courage great, and its fury irresistible; it must have three things belonging to the sheep—the nose, gentleness, and patience; it must have three of a deer—head, leg, and skin; it must have three of a wolf—throat, neck, and hearing; it must have three of a fox—ear, tail, and trot; three of a serpent—memory, sight, and flexibility; and, lastly, three of a hare—running, walking, and perseverance."

## CHAP. II.

### OF THE ASS.

Although this animal is very easily distinguished from the horse at first sight, yet upon closer inspection the similitude between them is very striking. They have both a similar outline in the external parts—the same conformation within. One would be led, from the great resemblance there is between them, to suppose them of the same species, and that the ass was only a horse degenerated; however, they are perfectly distinct, and there is an inseparable line drawn between them—for the mule they produce is barren. This seems to be the barrier between every species of animals; this keeps them asunder, and preserves the unities of their form. If the mule or the monster, bred between two animals whose form nearly approaches, is no longer fertile, we may then conclude that these animals, however resembling, are of different kinds. Nature has providently stopped the fruitfulness of these ill-formed productions, in order to preserve the form of every animal uncontaminated: were it not for this the races would quickly be mixed with each other; no one kind would preserve its original perfection; every creature would quickly degenerate; and the world would be stocked with imperfection and deformity.

The horse and the ass, therefore, though so nearly approaching in form, are of two distinct kinds, different in their natures; and were there but one of each kind both races would then be extinguished. Their shapes and their habits may, indeed, be very nearly alike; but there is something in every animal, besides its conformation or way of life, that determines its specific nature. Thus there is much greater resemblance between the horse and the ass than between the sheep and the goat; and yet the latter produce an animal that is by no means barren, but which quickly re-produces an offspring resembling the sheep; while the mule of the former is marked with certain sterility. The goat and the sheep may be therefore said to be of one kind, although so much unlike in figure; while the horse and the ass are perfectly distinct, though so closely resembling. It has, indeed, been said by Aristotle that their male is sometimes prolific; this, however, has not been confirmed by any other testimony, although there has elapsed a period of near two thousand years to collect the evidence.

But what tends to put the subject out of dispute is, that the two animals are found in a state of nature entirely different. The onager, or wild ass, is seen in still greater abundance than the wild horse; and the peculiarities of its kind are more distinctly marked than in those of the tame one. Had it been a horse degenerated, the likeness would be stronger between them the higher we went to the original stock from whence both have been supposed to be sprung. The wild animals of both kinds would in such a case resemble each other much more than those of the tame kind, upon whom Art has for a succession of ages been exercising all its force, and producing strange habits and new alterations. The contrary, however, obtains, and the wild ass is even more

assinine, if I may so express it, than that bred in a state of domestic servitude; and has even a natural aversion to the horse, as the reader will shortly learn.

The wild ass has by some writers been confounded with the zebra, but very improperly, for they are of a very different species. The wild ass is not streaked like the zebra, nor is his shape so beautiful: his figure is pretty much the same as that of the common ass, except that he is of a brighter colour, and has a white list running from his head to his tail. This animal is found wild in many islands of the Archipelago, particularly in that of Cerigo. There are many wild asses in the deserts of Lybia and Numidia, that run with such amazing swiftness that scarce even the coursers of the country can overtake them. When they see a man they set up a horrid braying, and stop short all together till he approaches near them; they then, as if by common consent, fly off with great speed; and it is upon such occasions that they generally fall into the traps which are previously prepared to catch them. The natives take them chiefly on account of their flesh, which they esteem as delicious eating; and for their skins, of which that kind of leather is made which is called "shagreen."

Olearius relates that the monarch of Persia invited him on a certain day to be present at an entertainment of a very peculiar nature, which was exhibited in a small building near the palace, resembling a theatre. After a collation of fruits and sweetmeats, more than thirty of these wild asses were driven into the area, among which the monarch discharged several shot and some arrows, and in which he was imitated by some of his immediate attendants. The asses, finding themselves wounded and no way of escaping, instantly began to attack each other, biting with great fierceness and braying terribly. In this manner they continued their mutual animosity, while the arrows were poured in from above until they were all killed; upon which they were ordered to be taken and sent to the king's kitchen at Ispahan. The Persians esteem the flesh of this animal so highly, that its delicacy is even become a proverb among them. What may be the taste of the wild ass's flesh we are unable to say; but certain it is that the flesh of the tame ass is the worst that can be obtained, being dryer, more tough, and more disagreeable than horse-flesh. Galen even says that it is very unwholesome. Yet we should not judge hastily upon the different tastes of different people in the preference they give to certain meats. The climate produces very great changes in the tenderness and savour of several viands: that beef, for instance, which is so juicy and good in England is extremely tough and dry when killed under the line; on the contrary, that pork which with us is so unpalatable in summer, in the warmer latitudes, where it is always hotter than here, is the finest eating they have, and much preferable to any hog's flesh in Europe.

The ass, like the horse, was originally imported into America by the Spaniards, and afterwards by other nations. That country seems to have been peculiarly favourable to this race of animals; and where they have run wild, they have multiplied in such numbers that in some places they have become a nuisance. In the kingdom of Quito, the owners of the grounds where they are bred suffer all persons to take away as many as they can, on paying a small acknowledgment in proportion to the number of days their sport lasts. They catch them in the following manner:—A number of persons go on horseback, and are attended by Indians on foot; when arrived at the proper places they form a circle, in order to drive them into some valley, where at full speed they throw the noose, and endeavour to halt them. These creatures, finding themselves enclosed, make vigorous efforts to escape; and if only one forces his way through they all follow with an irresistible impetuosity. When noosed, however, the hunters throw them down and secure them with fetters, and thus leave them

till the chase is over. Then, in order to bring them away with greater facility, they pair them with tame beasts of the same kind; but this is not so easily performed, for they are so remarkably fierce that they often hurt the persons who undertake to manage them. They have all the swiftness of horses, and neither declivities nor precipices can retard their career. When attacked, they defend themselves with their heels and mouth with such activity, that, without slackening their pace, they often maim their pursuers. But the most remarkable property in these creatures is, that after carrying their first load their celerity leaves them, their dangerous ferocity is lost, and they soon contract the stupid look and dullness peculiar to the assinine species. It is also observable that these creatures will not permit a horse to live among them: they always feed together; and if a horse happens to stray into the place where they graze they all fall upon him, and without giving him the liberty of flying, they bite and kick him till they kill him dead upon the spot.

Such is this animal in its natural state—swift, fierce, and formidable; but in his state of tameness the ass presents a very different picture; the moment his native liberty is repressed he seems entirely to give up all claims to freedom, and he assumes a patience and submission even humbler than his situation. He is in a state of tameness the most gentle and quiet of all animals. He suffers with constancy, and perhaps with courage, all the ill treatment that cruelty and caprice are pleased to inflict. He is temperate with regard to the quantity and the quality of his provision. He is contented with the most neglected weeds, and makes his humble repast upon what the horse and other animals leave behind. If he gives the preference to any vegetable, it is to the plantain; for which he is often seen to neglect every other herb in the pasture: but he is chiefly delicate with respect to his water; he drinks only at the clearest brooks, and chiefly those to which he has been accustomed. He drinks as soberly as he eats; and never, like the horse, dips his nose into the stream. As he is seldom saddled, he frequently rolls himself upon the grass, and lies down for this purpose as often as he has an opportunity, without minding what becomes of his burden. He never rolls, like the horse, in the mud; he even fears to wet his feet, and turns out of his way to avoid the dirty parts of the road.

When very young the ass is sprightly, and even tolerably handsome; but he soon loses these qualifications either by age or bad treatment, and he becomes slow, stupid, and headstrong. He seems to show no ardour except for the female, having been often known to die after the covering. The she-ass is not less fond of her young than the male is of her; and we are assured that she will cross fire and water to protect or rejoin them. This animal is sometimes not less attached to his owner, by whom he is too often abused. He scents him at a distance, and distinguishes him from others in a crowd; he knows the ways he has passed and the places where he inhabits.

When overloaded, the ass shows the injustice of his master by hanging down his head and lowering his ears; when he is too hard pressed, he opens his mouth and draws back his lips in a very disagreeable manner. If his eyes are covered he will not stir a step; and if he is laid down in such a manner that one eye is covered with the grass while the other is hidden with a stone, or whatever is next at hand, he will continue fixed in the same situation, and will not so much as attempt to rise to free himself from these slight impediments. He walks, trots, and gallops like a horse; but although he sets out very freely at first, yet he is soon tired—and then no beating will make him mend his pace. It is in vain that his unmerciful rider exerts his whip or his cudgel; the poor animal bears it all with patience, and, conscious of his own imbecility, does not offer even to move.

Notwithstanding the stupid heaviness of his air, he may be educated with as much ease as any other animal; and several have been brought up to perform, but have been neglected. Man despises this humble, useful creature, whose efforts are exerted to please him, and whose services are too cheaply purchased. The horse is the only favourite, and upon him alone all expense and labour are bestowed. He is fed, attended, and stabled, while the ass is abandoned to the cruelty of the lowest rustics, or even to the sport of children, and, instead of gaining by the lessons he receives, is always a loser. He is conducted along by blows; he is insulted by unnecessary stripes; he is overloaded by the lazy; and, being generally the property of the poor, he shares with them in their wants and their distresses. Thus this faithful animal—which, were there no horses, would be the first of the quadruped kind in our esteem—is now considered as nothing; his properties and qualifications being found in a higher degree elsewhere he is entirely disregarded; and, from being the second, he is degraded into one of the most useless of the domestic quadrupeds.

For this reason very little care has been taken to improve the breed; it is suffered to degenerate; and it is probable that of all other animals this alone is rendered feebler and more diminutive by being in a state of domestic servitude. The horse, the cow, and the sheep are rendered larger by the assiduity of man; the ass is suffered to dwindle every generation, and particularly in England, where it is probable that, but for the medicinal qualities of its milk, the whole species would have ere now been extinguished. Nevertheless, we have good reasons to believe that, were the same care bestowed on the ass that is spent upon the horse—were the same industry used in crossing the breed and improving it, we should see the ass become from his present mean state a very portly and serviceable animal; we should find him rival the horse in some of his perfections and exceed him in others. The ass, bulk for bulk, is stronger than the horse; is more sure footed; and, though more slow in his motions, he is much less apt to start out of the way.

The Spaniards, of all people in Europe, seem alone to be acquainted with the value of the ass. They take all proper precautions to improve the breed; and I have seen a jack-ass from that country above fifteen hands high. This animal, however, seems originally a native of Arabia. A warm climate is known to produce the largest and the best; their size and spirit decline in proportion as they advance into colder regions.

Though now so common in all parts of England, the ass was entirely lost amongst us during the reign of Queen Elizabeth. Holingshed informs us that our land "did yield no asses." However, there are accounts of their being common in England before that time. In Sweden they are at present a sort of rarity; nor does it appear by the last history of Norway that they have yet reached that country. It is in the hotter climates alone that we are to look for the original of this serviceable creature. In Guinea, they are larger and more beautiful than even the horses of the same country. In Persia they have two kinds—one of which is used for burdens, being slow and heavy; the other, which is kept for the saddle, being smooth, stately, and nimbler. They are managed as horses, only that the rider sits nearer the crupper; and they are taught to amble like them. They generally cleave their nostrils to give them more room for breathing, and many of these are sold for forty or fifty pounds.

The ass is a much more hardy animal than the horse, and liable to fewer diseases. Of all animals covered with hair he is the least subject to vermin, for he has no lice, probably owing to the dryness and the hardness of his skin. Like the horse, he is three or four years in coming to perfection; he lives till twenty or twenty-five, sleeps much less than the horse, and never lies down for

sleeps much less than the horse, and never lies down for that purpose unless very much tired. The she-ass goes above eleven months with young, and never brings forth more than one at a time. The mule may be engendered either between a horse and a she-ass, or between a jack-ass and a mare. The latter breed is very preferable, being larger, stronger, and better shaped. It is not yet well known whether the animal called the Gimmerro be one of these kinds; or, as is asserted, bred between the ass and the bull. While naturalists affirm the impossibility of this mixture, the natives of the Alpine countries, where this animal is bred, as strongly insist upon its reality. The common mule is very healthy, and will live above thirty years, being found very serviceable in carrying burdens, particularly in mountainous and stony places, where horses are not so sure footed. The size and strength of our asses is at present greatly improved by the importation of Spanish jack-asses; and it is probable we may come in time to equal the Spaniards in breeding them, where it is not uncommon to give fifty or sixty guineas for a mule; and, indeed, in some mountainous countries the inhabitants cannot well do without them. Their manner of going down the precipices of the Alps or the Andes is very extraordinary; and with it we will conclude their history. In these passages, on one side are steep eminences, and on the other frightful abysses; and, as they generally follow the direction of the mountain, the road, instead of lying in a level, forms at every little distance steep declivities of several hundred yards downward. These can only be descended by mules; and the animal itself seems sensible of the danger, and the caution that is to be used in such descents. When they come to the edge of one of these descents they stop without being checked by the rider; and if he inadvertently attempts to spur them on they continue immovable. They seem all this time ruminating on the danger that lies before them, and preparing themselves for the encounter. They not only attentively view the road, but tremble and snort at the danger. Having prepared for the descent, they place their fore-feet in a posture as if they were stopping themselves; they then also put their hinder-feet together, but a little forward, as if they were going to lie down. In this attitude, having taken as it were a survey of the road, they slide down with the swiftness of a meteor. In the meantime, all the rider has to do is to keep himself fast on the saddle without checking the rein, for the least motion is sufficient to disorder the equilibrium of the mule, in which case they both unavoidably perish. But their address in this rapid descent is truly wonderful; for in their swiftest motion, when they seem to have lost all government of themselves, they follow exactly the different windings of the road as if they had previously settled in their minds the route they were to follow, and taken every precaution for their safety. In this journey the natives, who are placed along the sides of the mountains, and hold by the roots of the trees, animate the beasts with shouts, and encourage them to perseverance. Some mules, after being long used to these journeys, acquire a kind of reputation for their safety and skill; and their value rises in proportion to their fame.

### CHAP. III.

#### OF THE ZEBRA.

There are but three animals of the horse kind—the horse, which is the most stately and courageous; the ass, which is the most patient and humble; and the zebra, which is the most beautiful, but at the same time the wildest animal in nature. Nothing can exceed the delicate regularity of this creature's colour, or the lustrous smoothness of its skin; but, on the other hand, nothing can be more timid or more untameable.

It is chiefly a native of the southern parts of Africa; and there are whole herds of them often seen feeding in those extensive plains that lie towards the Cape of Good Hope. However, their watchfulness is such that they will suffer nothing to come near them, and their swiftness so great that they readily leave every pursuer far behind. The zebra in shape rather resembles the mule than the horse or the ass; it is rather less than the former, and yet larger than the latter; its ears are not so long as those of the ass, and yet not so small as in the horse kind. Like the ass, its head is large, its back straight, its legs finely placed, and its tail tufted at the end; like the horse, its skin is smooth and close, and its hind quarters round and fleshy. But its greatest beauty lies in the amazing regularity and elegance of its colours. In the male they are white and brown—in the female white and black. These colours are disposed in alternate stripes over the whole body, and with such exactness and symmetry, that one would think Nature had employed the rule and compass to paint them. These stripes—which, like so many ribands, are laid all over its body—are narrow, parallel, and exactly separated from each other. It is not here, as in other partly coloured animals, where the tints are blended into each other; every stripe here is perfectly distinct, and preserves its colour round the body or the limb without any diminution. In this manner are the head, the body, the thighs, the legs, and even the tail and the ears beautifully streaked—so that at a little distance one would be apt to suppose that the animal was dressed out by Art, and not thus admirably adorned by Nature.

In the male zebra the head is striped with fine bands of black and white, which in a manner centre in the forehead; the ears are variegated with a white and dusky brown; the neck has broad stripes of the same dark brown running round it, leaving narrow white stripes between. The body is also striped across the back with broad bands, leaving narrow spaces of white between them, and ending in points at the sides of the belly, which is white, except a black line peccinated on each side, reaching from between the fore-legs along the middle of the belly two-thirds of its length. There is a fine separation between the trunk of the body and the hinder quarters on each side; behind which, on the rump, is a plait of narrow stripes, joined together by a stripe down the middle to the end of the tail. The colours are different in the female; and in none the stripes seem entirely to agree in form, but in all they are equally distinct, the hair equally smooth and fine, the white shining and unmixed, and the black or brown thick and lustrous.

Such is the beauty of this creature, that it seems by Nature fitted to satisfy the pride and the pleasure of man, and formed to be taken into his service. Hitherto, however, it appears to have disdained servitude, and neither force nor kindness have been able to wean it from its native independence and ferocity. But this wildness might, perhaps, in time be surmounted; and it is probable the horse and the ass when first taken from the forest were equally obstinate, fierce, and unmanageable. Mr. Buffon informs us that the zebra, from which he took his description, could never be entirely mastered, notwithstanding all the efforts which were tried to tame it. They continued, indeed, to mount it, but then with such precautions as evidently showed its fierceness—for two men were obliged to hold the reins while the third ventured upon its back; and even then it attempted to kick whenever it perceived any person approaching. That which is now in the Queen's menagerie at Buckingham-gate is even more vicious than the former; and the keeper who shows it takes care to inform the spectators of its ungovernable nature. Upon my attempting to approach it seemed quite terrified, and was preparing to kick, appearing as wild as if just caught, although taken extremely young, and used with the utmost in-

disageance. Yet still it is most probable that this animal by time and assiduity could be brought under subjection. As it resembles the horse in form, without all doubt it has a similitude of nature, and only requires the efforts of an industrious and skilful nation to be added to the number of our domestics. It is not known what were the pains and dangers which were first undergone to reclaim the breed of horses from savage ferocity; they, no doubt, made an equal opposition; but by being opposed by an industrious and enterprising race of mankind, their spirit was at last subdued and their freedom restrained. It is otherwise with regard to the zebra; it is a native of countries where the human inhabitants are but little raised above the quadruped. The natives of Angola or Caffraria have no other idea of advantage from horses but as they are good for food; neither the fine stature of the Arabian courser nor the delicate colourings of the zebra have any allurements to a race of people who only consider the quantity of flesh, and not its conformation. The delicacy of the zebra's shape or the painted elegance of its form are no more regarded by such than by the lion that makes it his prey. For this reason, therefore, the zebra may have hitherto continued wild because it is a native of a country where there have been no successful efforts made to reclaim it. All pursuits that have hitherto been instituted against it were rather against its life than its liberty; the animal has thus been long taught to consider man as its mortal enemy; and it is not to be wondered that it refuses to yield obedience where it has so seldom experienced mercy. There is a kind of knowledge in all animals that I have often considered with amazement—which is, that they seem perfectly to know their enemies, and to avoid them. Instinct, indeed, may teach the deer to fly from the lion, or the mouse to avoid the cat; but what is the principle that teaches the dog to attack the dog-butcher wherever he sees him? In China, where the killing and dressing dogs is a trade, whenever one of these people moves out all the dogs of the village or street are sure to be after him. This I should scarcely have believed, but that I have seen more than one instance of it among ourselves. I have seen a poor fellow, who made a practice of stealing and killing dogs for their skins, pursued in full cry for three or four streets together by all the bolder breed of dogs, while the weaker flew from his presence with affright. How these animals could thus find out their enemy and pursue him appears, I own, unaccountable; but such is the fact; and it not only obtains in dogs but in several other animals, though perhaps to a less degree. This probably may have been in some measure a cause that has heretofore kept the zebra in its state of natural wildness, and in which it may continue till kinder treatment shall have reconciled it to its pursuers.

It is likely, therefore, as a more civilised people are now placed at the Cape of Good Hope (which is the chief place where this animal is found), that we may have them tamed and rendered serviceable. Nor is its extraordinary beauty the only motive we have for wishing this animal among the number of our dependents: its swiftness is said to surpass that of all other animals; so that the speed of the zebra is become a proverb among the Spaniards and Portuguese. It stands better upon its legs than the horse, and is consequently stronger in proportion. Thus, if by proper care we improved the breed as we have in other instances, we should probably in time to come have a race as large as the horse—as fleet, as strong, and much more beautiful.

The zebra, as was said, is chiefly a native of the Cape of Good Hope. It is also found in the kingdom of Angola, and also, as we are assured by Lopez, in several provinces of Barbary. In those boundless forests it has nothing to restrain its liberty; it is too shy to be caught in traps, and therefore seldom taken alive. It would seem, therefore, that none of them have ever been brought

into Europe that were caught sufficiently young so as to be untinctured by their original state of wildness. The Portuguese, indeed, pretend that they have been able to tame them, and that they have sent four from Africa to Lisbon, which were so far brought under as to draw the king's coach: they add, that the person who sent them over had the office of notary conferred upon him for his reward, which was to remain to him and his posterity for ever; but I do not find this confirmed by any person who says he saw them. Of those which were sent to Brazil not one could be tamed; they would permit one man only to approach them; they were tied up very short; and one of them, which had by some means got loose, actually killed his groom, having bitten him to death. Notwithstanding this, I believe, were the zebra taken up very young and properly treated, it might be rendered as tame as any other animal; and Merolla, who saw many of them, asserts, that when tamed, which he speaks of as being common enough, they are not less estimable for their swiftness than their beauty.

This animal, which is neither to be found in Europe, Asia, nor America, is nevertheless very easily fed. That which came over to England some years ago would eat almost anything, such as bread, meat, and tobacco; that which is now among us subsists entirely upon hay. As it so nearly resembles the horse and the ass in structure, so it probably brings forth annually as they do. The noise they make is neither like that of a horse nor an ass, but more resembling the confused barking of a mastiff dog. In the two which I saw there was a circumstance that seems to have escaped naturalists; which is, that the skin hangs loose below the jaw upon the neck, in a kind of dewlap, which takes away much from the general beauty; but whether this be a natural or accidental blemish I will not take upon me to determine.

These animals are often sent as presents to the princes of the east. We are told that one of the governors of Batavia gave a zebra, which had been sent to him from Africa, to the emperor of Japan, for which he received as an equivalent for the company a present to the value of sixty thousand crowns. Teller also relates that the Great Mogul gave two thousand ducats for one of them; and it is frequent with the African ambassadors to the court of Constantinople to bring some of these animals with them as presents for the Grand Signior.

## OF RUMINATING ANIMALS.

### BOOK II.—CHAP. I.

INTRODUCTION.—Of all animals, those that chew the cud are the most harmless and the most easily tamed. As they live entirely upon vegetables, it is neither their interest nor their pleasure to make war upon the rest of the brute creation; content with the pastures where they are placed, they seldom desire to change while they are furnished with a proper supply; and, fearing nothing from each other, they generally go in herds for their mutual security. All the fiercest of the carnivorous kinds seek their food in gloomy solitude; these, on the contrary, range together; the very meanest of them are found to unite in each other's defence; and the hare itself is a gregarious animal in those countries where it has no other enemies but the beasts of the forest to guard against.

As the food of ruminant animals is entirely of the vegetable kind, and as this is very easily procured, so these animals seem naturally more indolent and less artful than those of the carnivorous kinds; and as their appetites are more simple their instincts seem less capable of variation. The fox or the wolf are for ever prowling; their long habits of want give them a degree

of sharpness and cunning; their life is a continued scene of stratagem and escape; but the patient ox or the deer enjoy the repast that Nature has abundantly provided—certain of subsistence, and content with security.

As Nature has formed these animals with an appetite for such coarse and simple nutriment, so she has enlarged the capacity of the intestines to take in a greater supply. In the carnivorous kinds, as their food is nourishing and juicy their stomachs are but small and their intestines short; but in these, whose pasture is coarse, and where much must be accumulated before any quantity of nourishment can be obtained, their stomachs are large and numerous, and their intestines long and muscular. The bowels of a ruminating animal may be considered as an elaboratory, with vessels in it fitted for various transmutations. It requires a long and tedious process before grass can be transformed into flesh; and, for this purpose, Nature in general has furnished such animals as feed upon grass with four stomachs, through which the food successively passes and undergoes the proper separations.

Of the four stomachs with which ruminant animals are furnished, the first is called the "paunch," which receives the food after it has been slightly chewed; the second is called the "honeycomb," and is properly nothing more than a continuation of the former: these two, which are very capacious, the animal fills as fast as it can, and then lies down to ruminate—which may be properly considered a kind of vomiting without effort or pain. The two stomachs above-mentioned being filled with as much as they can contain, and the grass which was slightly chewed beginning to swell with the heat of the situation, it dilates the stomachs, and these again contract upon their contents. The aliment thus squeezed has but two passages to escape at—one into the third stomach, which is very narrow, and the other back by the gullet into the mouth, which is wider. The greatest quantity, therefore, is driven back through the largest aperture into the mouth to be chewed a second time; while a small part, and that only the most liquid, is driven into the third stomach through the orifice which is so small. The food which is driven to the mouth and chewed a second time is thus rendered more soft and moist, and becomes at last liquid enough to pass into the conduit that goes to the third stomach, where it undergoes a still farther comminution. In this stomach, which is called the "manyfold," from the number of its leaves, all which tend to promote digestion, the grass has the appearance of boiled spinage, but not yet sufficiently reduced so as to make a part of the animal's nourishment: it requires the operation of the fourth stomach for this purpose, where it undergoes a complete maceration, and is separated to be turned into chyle.

But Nature has not been less careful in another respect in fitting the intestines of these animals for their food. In the carnivorous kinds they are thin and lean; but in ruminating animals they are strong, fleshy, and well covered with fat. Every precaution seems taken that can help their digestion: their stomach is strong and muscular, the more readily to act upon its contents; their intestines are lined with fat, the better to preserve their warmth; and they are extended to a much greater length, so as to extract every part of that nourishment which their vegetable food so scantily supplies.

In this manner are all quadrupeds of the cow, the sheep, or the deer kind seen to ruminate—being thus furnished with four stomachs for the macerating of their food. These, therefore, may most properly be called the "ruminant" kinds; although there are many others that have this quality in a less observable degree. The rhinoceros, the camel, the horse, the rabbit, the marmotte, and the squirrel, all chew their cud by intervals, although they are not furnished with stomachs like the former. But not these alone, there are numberless other animals that appear to ruminate—not only birds, but fishes and

insects. Among birds are the pelican, the stork, the heron, the pigeon, and the turtle; these have a power of disgorging their food to feed their young. Among fishes are lobsters, crabs, and that fish called the "dorado." The salmon also is said to be of this number: and, if we may believe Ovid, the scarus likewise; of which he says—

Of all the fish that graze beneath the seed,  
He only ruminates his former food.

Of insects, the ruminating tribe is still larger—the mole, the cricket, the wasp, the drone, the bee, the grasshopper, and the beetle. All these animals either actually chew the cud or seem at least to ruminate. They have the stomach composed of muscular fibres, by means whereof the food is ground up and down in the same manner as in those which are particularly distinguished by the appellation of "ruminants."

But not these alone; men themselves have been often known to ruminate, and some even with pleasure. The accounts of these calamities (for such I must consider them) incident to our fellow-creatures are not very pleasant to read; yet I must transcribe a short one, as given us by *Slare* in the *Philosophical Transactions*, as it may in some measure show the satisfaction which the lower tribes of animals enjoy while they ruminate. The man in question was a citizen of Bristol, of about twenty years of age, and, what seemed more extraordinary still, of a ruminating family, for his father was subject to the same infirmity, or amusement, as he himself perhaps would call it. This young man usually began to chew his meat over again within about a quarter of an hour after eating. His ruminating after a full meal generally lasted about an hour and a half; nor could he sleep until his task was performed. The victuals upon the return tasted even more pleasantly than at first; and returned as if they had been beaten up in a mortar. If he ate a variety of things, that which he ate at first came up again first; and if this return was interrupted for any time it produced sickness and disorder, and he was never well till it returned. Instances of this kind, however, are rare and accidental; and it is happy for mankind that they are so. Of all other animals man spends the least time in eating; this is one of the great distinctions between us and the brute creation; and eating is a pleasure of so low a kind, that none but such as are nearly allied to the quadruped desire its prolongation.

## CHAP. II

### OF QUADRUPEDS OF THE COW KIND.

Of all ruminating animals that of the cow kind deserves the first rank, both for its size, its beauty, and its services. The horse is more properly an animal belonging to the rich; the sheep chiefly thrives in a flock, and requires attendance; but the cow is more especially the poor man's pride, his riches, and his support. There are many of our peasantry that have no other possession than a cow; and even of the advantages resulting from this most useful creature the poor are but the nominal possessors. Its flesh they cannot pretend to taste, since then their whole riches would be at once destroyed; its calf they are obliged to fatten for sale, since veal is a delicacy they could not make any pretensions to; its very milk is wrought into butter and cheese for the tables of their masters. While they have no share even in their own possession but the choice of their market, I cannot bear to hear the rich crying out for liberty while they thus starve their fellow-creatures, and feed them up with an imaginary good while they monopolise the real benefits of Nature.

In those countries where the men are under better subordination this excellent animal is of more general

advantage. In Germany, Poland, and Switzerland every peasant keeps two or three cows, not for the benefit of his master but of himself. The meanest of the peasants there kills one cow at least for his own table, which he salts and hangs up, and thus preserves as a delicacy all the year round. There is scarce a cottage in all those countries that is not hung round with these marks of hospitality, and which often make the owner better contented with hunger, since he has it in his power to be luxurious when he thinks proper. A piece of beef hung up there is considered as an elegant piece of furniture, which, though seldom touched, at least argues the possessor's opulence and ease. But it is very different for some years past in this country, where our lower rustics at least are utterly unable to purchase meat any part of the year; and by them even butter is considered as an article of extravagance.

The climate and pasture of Great Britain, however, is excellently adapted to this animal's moderate nature; and the verdure and fertility of our plains are perfectly suited to the manner of its feeding—for, wanting the upper fore-teeth, it loves to graze in a high rich pasture. This animal seems but little regardful of the quality of its food provided it be supplied in sufficient abundance; it makes no particular distinctions in the choice of its herbage, but indiscriminately and hastily devours the proper quantity. For this reason, in our pastures—where the grass is rather high than succulent, and more flourishing than nutritious—the cow thrives admirably; and there is no part of Europe where the tame animal grows larger, yields more milk, and more readily fattens than with us.

Our pastures supply them with abundance, and they in return enrich the pasture; for of all animals the cow seems to give back more than it takes from the soil. The horse and the sheep are known in a course of years to impoverish the ground: the land where they have fed becomes weedy, and the vegetables coarse and unpalatable. On the contrary, the pasture where the cow has been bred acquires a finer, softer surface, and becomes every year more beautiful and even. The reason is, that the horse, being furnished with fore-teeth in the upper jaw, nips the grass closely, and therefore only chooses that which is the most delicate and tender; the sheep also—though, with respect to its teeth, formed like the cow—only bites the most succulent parts of the herbage. These animals, therefore, leave all the high weeds standing; and, while they cut the finer grass too closely, suffer the rank herbage to vegetate and overrun the pasture. But it is otherwise with the cow; as its teeth cannot come so close to the ground as those of the horse, nor so readily as those of the sheep, which are less, it is obliged to feed upon the tallest vegetables that offer; thus it eats them all down, and in time levels the surface of the pasture.

The age of the cow is known by its teeth and horns. This animal is furnished with eight cutting teeth in the lower jaw; at the age of ten months the two middlemost of these fall out, and are replaced with others that are not so white, but broader; at the age of sixteen months the two next milk-white teeth fall out also, and others come up in their room: thus, at the end of every six months the creature loses and gains, till, at the age of three years, all the cutting teeth are renewed, and then they are long, pretty white, and equal; but in proportion as the animal advances in years they become irregular and black, their inequalities become smoother, and the animal less capable of chewing its food. Thus the cow often declines from this single cause; for as it is obliged to eat a great deal to support life, and as the smoothness of the teeth makes the difficulty of chewing great, a sufficient quantity of food cannot be supplied to the stomach. Thus the poor animal sinks in the midst of plenty, and every year grows leaner and leaner, till it dies.

The horns are another, and a surer, method of determining this animal's age. At three years old it sheds its horns, and new ones arise in their place, which continue as long as it lives; at four years of age the cow has small, pointed, neat smooth horns, thickest near the head; at five the horns become larger, and are marked round with the former year's growth. Thus, while the animal continues to live the horns continue to lengthen, and every year a new ring is added at the root; so that allowing three years before their appearance, and then reckoning the number of rings, we have in both together the animal's age exactly.

As we have indisputably the best breed of horned cattle of any in Europe, so it was not without the same assiduity that we came to excel in these as in our horses. The breed of cows has been entirely improved by a foreign mixture, properly adapted to supply the imperfections of our own. Such as are purely British are far inferior in size to those in many parts of the continent; but those which we have thus improved by far excel all others. Our Lincolnshire kind derive their size from the Holstein breed; and the large hornless cattle that are bred in some parts of England came originally from Poland. We were once famous for a wild breed of these animals, but they have long since been worn out; and perhaps no kingdom in Europe can furnish so few wild animals of all kinds as our own. Cultivation and agriculture are sure to banish these wherever they are found; and every addition a country receives from Art drives away those animals that are only fitted for a state of Nature.

Of all quadrupeds, the cow seems most liable to alteration from its pasture. In the different parts of our own country we easily perceive the great varieties produced among these animals by the richness or poverty of the soil. In some they grow to a great bulk; and I have seen an ox sixteen hands high, which is taller than the general run of our horses. In others they appear as diminutive, being not so large as an ass. The breed of the Isle of Man and most parts of Scotland is much less in general than in England or Ireland; they are different shaped also, the dewlap being much smaller, and, as the expression is, the beast has more of the ewe neck. This till some years ago was considered in cattle as a deformity, and the cow was chosen, according to Virgil's direction, with a large dewlap; however, at present it is the universal opinion that the cow wants in under what it has in neck, and the larger the dewlap the smaller is the quantity of its milk. Our graziers now, therefore, endeavour to mix the two breeds—the large Holstein with the small northern; and from both results that fine milch breed which excels the cattle of any other part of the world.

This difference, arising from pasture, is more observable in other countries than in our own. The cow kind is to be found in almost every part of the world large in proportion to the richness of the pasture, and small as the animal is stunted in its food. Thus Africa is remarkable for the largest and the smallest cattle of this kind; as is also India, Poland, Switzerland, and several other parts of Europe. Among the Eluth Tartars, where the pastures are remarkably rich and nourishing, the cow becomes so large that he must be a tall man who can reach the tip of its shoulder. On the contrary, in France, where the animal is stunted in its food and driven from the most flourishing pastures, it greatly degenerates.

But the differences in the size of this animal are not so remarkable as those which are found in its form, its hair, and its horns. The difference is so very extraordinary in many of them that they have been even considered as a different kind of creature, and names have been given them as a distinct species, when in reality they are all the same. In this manner the urus and the bison have been considered, from the variety in their

make, to be distinct in their production; but they are all, in fact, the descendants of one common stock, as they have that certain mark of unity, they breed and propagate among each other. Naturalists have therefore laboured under an obvious error, when, because of the extreme bulk of the urus, or because of the hump upon the back of the bison, they assigned them different places in the creation, and separated a class of animals which was really united. It is true, the horse and the ass do not differ so much in form as the cow and the bison; nevertheless, the former are distinct animals, as their breed is marked with sterility; the latter are animals of the same kind, as their breed is fruitful, and a race of animals is produced in which the hump belonging to the bison is soon worn away. The differences, therefore, between the cow, the urus, and the bison are merely accidental. The same caprices in Nature that has given horns to some cows and denied them to others may also have given the bison a hump, or increased the bulk of the urus; it may have given the one a mane, or denied a sufficiency of hair to the other.

But before we proceed farther, it may be proper to describe these varieties which have been thus taken for distinct kinds. The urus, or wild bull, is chiefly to be met with in the province of Lithuania, and grows to a size that scarce any other animal except the elephant is found to equal. It is quite black, except a stripe mixed with white, that runs from the neck to the tail along the top of the back; the horns are short, thick, and strong; the eyes are fierce and fiery; the forehead is adorned with a kind of garland of black curled hair, and some of them are found to have beards of the same; the neck is short and strong, and the skin has an odour of musk. The female, though not so big as the male, exceeds the largest of our bulls in size; nevertheless, her udder and teats are so small that they can scarcely be perceived. Upon the whole, however, this animal resembles the tame one very exactly, except in some trifling varieties, which his state of wildness or the richness of the pastures where he is found may easily have produced.

The bison, which is another variety of the cow kind, differs from the rest in having a lump between its shoulders. These animals are of various kinds—some very large, others as diminutively little. In general, to regard this animal's fore-parts he has somewhat the look of a lion, with a long shaggy mane, and a beard under his chin; his head is little, his eyes red and fiery, with a furious look; the forehead is large, and the horns so big and so far assunder, that three men might often sit between them. On the middle of the back there grows a hump almost as high as that of a camel, covered with hair, and which is considered as a great delicacy by those that hunt him. There is no pursuing him with safety, except in forests where there are trees large enough to hide the hunters. He is generally taken by pit-falls—the inhabitants of those countries where he is found wild digging holes in the ground, and covering them over with boughs of trees and grass; then provoking the bison to pursue them, they get on the opposite side of the pit-fall, while the furious animal, running head foremost, falls into the pit prepared for him, and is there quickly overcome and slain.

Besides these real distinctions in the cow kind, there have been many others made that appear to be in name only. Thus the *bonasus*, of which naturalists have given us long descriptions, is supposed by Klein and Buffon to be no more than another name for the bison, as the descriptions given of them by the ancients coincide. The *bubalus*, also, of the ancients, which some have supposed to belong to the cow kind, Buffon places among the lower class of ruminant quadrupeds, as it most resembles them in size, shape, and the figure of its horns. Of all the varieties, therefore, of the cow kind there are but two that are really distinct—namely, the cow and the buffalo; these two are separated by Nature; they

seem to bear an antipathy to each other; they avoid each other, and may be considered as much removed as the horse is from the ass or the zebra. When, therefore, we have described the varieties of the cow kind we shall pass on to the buffalo, which being a different animal requires a separate history.

There is scarce a part of the world, as was said before, in which the cow is not found in some one of its varieties—either large, like the urus, or humped, as the bison; with straight horns, or bending, inverted backwards, or turning sideways to the cheek like those of a ram; and in many countries they are found without any horns whatsoever. But to be more particular, beginning at the north, the few kine which subsist in Iceland are without horns, although of the same race originally with our own. The size of these is rather relative to the goodness of the pasture than the warmth or coldness of the climate. The Dutch frequently bring great quantities of lean cattle from Denmark, which they fatten on their own rich grounds. These are in general of a larger size than their own natural breed, and they fatten very easily. The cattle of Ukraine, where the pasture is excellent, become very fat, and are considered as one of the largest breeds in Europe. In Switzerland, where the mountains are covered with a rich nourishing herbage, which is entirely reserved for the kine, these animals grow to a very large size. On the contrary, in France, where they get no other grass but what is thought unfit for horses, they dwindle and grow lean. In some parts of Spain the cow grows to a good size; those wild bulls, however, which they pride themselves so much in combating, are a very mean, despicable little animal, and somewhat shaped like one of our cows, with nothing of that peculiar sternness of aspect for which our bulls are remarkable. In Barbary and the provinces of Africa, where the ground is dry and the pasturage short, the cows are of a very small breed, and give milk in proportion. On the contrary, in Ethiopia they are of a prodigious size. The same holds in Persia and Tartary, where in some places they are very small, and in others of an amazing stature. It is thus in almost every part of the world this animal is found to correspond in size to the quantity of its provision.

If we examine the form of these animals as they are found tame in different regions, we shall find that the breed of the urus, or those without a hump, chiefly occupies the cold and the temperate zones, and is not so much dispersed towards the south. On the contrary, the breed of the bison, or the animal with a hump, is found in all the southern parts of the world—throughout the vast continent of India—throughout Africa, from Mount Atlas to the Cape of Good Hope. In all these countries the bison seems chiefly to prevail, where they are found to have a smooth soft hair, are very nimble of foot, and in some measure supply the want of horses. The bison breed is more expert and docile than ours; many of them when they carry burdens bend their knees to take them up or let them down: they are treated, therefore, by the natives of those countries with a degree of tenderness and care equal to their utility; and the respect for them in India has degenerated even into blind adoration. But it is among the Hottentots where these animals are chiefly esteemed, as being more than commonly serviceable. They are their fellow-domestics—the companions of their pleasures and fatigues; the cow is at once the Hottentot's protector and servant, assists him in attending his flocks, and guarding them against every invader; while the sheep are grazing the faithful bakely, as this kind of cow is called, stands or grazes beside them: still, however, attentive to the looks of its master, the bakely flies round the field, herds in the sheep that are straying, obliges them to keep within proper limits, and shows no mercy to robbers, or even strangers, who attempt to plunder. But it is not the plunderers of the flock alone, but even the enemies of the

nation that these backelies are taught to combat. Every army of Hottentots is furnished with a proper herd of these, which are let loose against the enemy when the occasion is most convenient. Being thus sent forward they overturn all before them; they strike every opposer down with their horns, and trample upon them with their feet; and thus often procure their masters an easy victory, even before they have attempted to strike a blow. An animal so serviceable, it may be supposed, is not without its reward. The backely lives in the same cottage with its master, and, by long habit, gains an affection for him; and in proportion as the man approaches to the brute, so the brute seems to attain even to some share of human sagacity. The Hottentot and his backely thus mutually assist each other; and when the latter happens to die, a new one is chosen to succeed him by a council of the old man of the village. The new backely is then joined with one of the veterans of his own kind, from whom he learns his art, becomes social and diligent, and is taken for life into human friendship and protection.

The bison, or cows with a hump, are found to differ very much from each other in the several parts of the world where they are found. The wild ones of this kind, as with us, are much larger than the tame. Some have horns, and some are without any; some have them depressed, and some raised in such a manner that they are used as weapons of annoyance or defence; some are extremely large, and others among them, such as the zebu or Barbary cow, are very small. They are all, however, equally docile and gentle when tamed, and in general furnished with a fine lustrous soft hair, more beautiful than that of our own breed; their hump is also of different sizes, in some weighing from forty to fifty pounds, in others less; it is not, however, to be considered as a part necessarily belonging to the animal; and probably it might be cut away without much injury: it resembles a gristly fat; and, as I am assured, cuts and tastes somewhat like a dressed udder. The bison of Malabar, Abyssinia, and Madagascar are of the great kind, as the pastures there are plentiful. Those of Arabia, Petraea, and most parts of Africa are small, and of the zebu or little kind. In America, especially towards the north, the bison is well known. The American bison, however, is found to be rather less than that of the ancient continent; its hair is longer and thicker, its beard more remarkable, and its hide more lustrous and soft. There are many of them brought up tame in Carolina; however, their wild dispositions still seem to continue, for they break through all fences to get into the corn-fields, and lead the whole tame herd after them wherever they penetrate. They breed, also, with the tame kinds originally brought over from Europe, and thus produce a race peculiar to that country.

From all this it appears that naturalists have given various names to animals in reality the same, and only differing in some few accidental circumstances. The wild cow and the tame, the animal belonging to Europe, and that of Asia, Africa, and America, the bonasus and the urus, the bison and the zebu, are all one and the same, propagate among each other, and in the course of a few generations the hump wears away, and scarce any remains of savage fierceness are found to remain. Of all animals, therefore, except man alone, the cow seems most extensively propagated. Its nature seems equally capable of the rigours of heat and cold. It is an inhabitant as well of the frozen fields of Iceland as the burning deserts of Lybia. It seems an ancient inmate in every climate, domestic and tame in those countries which have been civilised, savage and wild in the countries which are less peopled, but capable of being made useful in all: able to defend itself in a state of nature against the most powerful enemy of the forest; and only subordinate to man, whose force it has experienced, and whose aid it at last seems to require. However wild the calves are, which are taken from the dam in a savage

state, either in Africa or Asia they soon become humble, patient, and familiar; and man may be considered, in those countries, as almost helpless without their assistance. Other animals preserve their nature or their form with inflexible perseverance; but these, in every respect, suit themselves to the appetites and conveniences of mankind; and as their shapes are found to alter, so also does their nature; and in no animal is their seen a greater variety of kinds, and in none a more humble and pliant disposition.

**THE BUFFALO.**—If we should compare the shape of our common cow with that of the bison, the difference will appear very great. The shaggy mane of the latter, the beard, the curled forehead, the inverted horns, the broad breast, and the narrow hinder parts, give it the appearance rather of a lion than a cow, and fit it more for a state of war with mankind than a state of servitude. Yet, notwithstanding these appearances, both animals are found to be the same—or at least so nearly allied that they breed among each other, and propagate a race that continues the kind.

On the other hand, if we compare the buffalo with our common cow, no two animals can be more alike either in their form or their nature—both equally submissive to the yoke, both often living under the same roof and employed in the same domestic services—the make and the turn of their bodies so much alike that it requires a close attention to distinguish them; and yet, after all this, no two animals can be more distinct, or seem to have stronger antipathies to each other. Were there but one of each kind remaining, it is probable the race of both would shortly be extinct. However, such is the fixed aversion formed between these creatures, that the cow refuses to breed with the buffalo, which it nearly resembles; while it is known to propagate with the bison, to which it has, in point of form, but a distant similitude.

The buffalo is, upon the whole, by no means so beautiful a creature as the cow; his figure is more clumsy and awkward; his air is wilder; and he carries his head lower and nearer the ground; his limbs are less fleshy; and his tail more naked of hair; his body is shorter and thicker than that of the cow kind; his legs are higher; his head smaller; his horns not so round, black, and compressed, with a bunch of curled hair hanging down between them; his skin is also harder and thicker, more black, and less furnished with hair; his flesh, which is hard and blackish, is not only disagreeable to the taste, but likewise to the smell. The milk of the female is by no means so good as that of the cow; it is, however, produced in great abundance. In the warm countries almost all their cheese is made of the milk of the buffalo; and they also supply butter in large quantities. The veal of the young buffalo is not better eating than the beef of the old. The hide of this animal seems to be the most valuable thing he furnishes. The leather made of it is well known for its thickness, softness and impenetrability. As these animals are in general larger and stronger than the cow, they are usefully employed in agriculture. They are used in drawing burdens, and sometimes in carrying them—being guided by a ring, which is thrust through their nose. Two buffaloes yoked in a waggon are said to draw more than four strong horses; as their heads and necks are naturally bent downward, they are thus better fitted for the draught, and the weight of their bodies is applied to the carriage that is to be drawn forward.

From the size and bulk of the buffalo, we may be easily led to conclude that he is a native of the warmer climates. The largest quadrupeds are generally found in the torrid zone: and the buffalo is inferior in point of size only to the elephant, the rhinoceros, or the hippopotamus. The cameloopard or the camel may, indeed, be taller, but they are neither so long nor near so corpulent. Accordingly,

we find this animal wild in many parts of India; and tamed, also, wherever the natives have occasion for his services. The wild buffaloes are very dangerous animals, and are often found to gore travellers to death, and then trample them with their feet until they have entirely mangled the whole body: however, in the woods they are not so much to be feared as in the plains, because in the violence of their pursuit their large horns are apt to be entangled in the branches of the trees, which gives those who have been surprised by them time to escape the danger. There is scarce any other method of avoiding their pursuit; they run with great swiftness; they overturn a tree of moderate growth; and are such swimmers, as to cross the largest rivers without any difficulty. In this manner, like other large animals of the torrid zone, they are very fond of the water; and, in the midst of their pursuit, often plunge in in order to cool themselves. The Negroes of Guinea and the Indians of Malabar, where buffaloes are in great abundance, take great delight in hunting and destroying them; however, they never attempt to face the buffalo openly, but, generally climbing up the tree, shoot at him from thence, and do not come down till they find they have effectually despatched him. When they are tamed, no animal can be more patient or humble; and though by no means so docile as the cow kind, yet they go through domestic drudgeries with more strength and perseverance.

Although these animals are chiefly found in the torrid zone, yet they are bred in several parts of Europe; particularly in Italy, where they make the food and the riches of the poor. The female produces but one at a time, in the same manner as the cow; but they are very different in the times of gestation—for the cow, as we know, goes but nine months, whereas the buffalo continues pregnant for twelve. They are all afraid of fire; and, perhaps, in consequence of this, have an aversion to red colours, or anything resembling the colour of flame. It is said that in those countries where they are found in plenty no person dares to dress in scarlet. In general they are inoffensive animals if undisturbed—as indeed all those which feed upon grass are found to be: but when they are wounded, or when even but fired at, nothing then can stop their fury; they turn up the ground with their fore-feet, bellow much louder and more terribly than the bull, and attack the object of their resentment with ungovernable rage. It is happy in such circumstances if the person they pursue has a wall over which to escape, or some such obstacle, otherwise they soon overtake and instantly destroy him. It is remarkable, however, that although their horns are so very formidable they in general make more use of their feet in combat, and rather tread their enemies to death than gore them.

Having thus gone through the history of these animals, it may be proper to observe that no names have been more indiscriminately used than those of the bull, the urus, the bison, and the buffalo. It therefore becomes such as would have distinct ideas of each to be careful in separating the kinds the one from the other, allowing the cow for the standard of all. The urus, whether of the large enormous kind of Lithuania or the smaller race of Spain—whether with long or short horns, or whether with or without long hair on the forehead, is every way the same with what our common breed was before they were taken from the forest and reduced to a state of servitude. The bison and all its varieties, which are known by a hump between the shoulders, is also to be ranked in the same class. This animal—whether with crooked or straight horns—whether they be turned towards the cheek or totally wanting, whether it be large or diminutive—whatever be its colour or whatever the length of its hair, whether called the “bonasus” by some or the “bubalus” by others—is but a variety of the cow kind, with whom it breeds, and with whom of consequence it has the closest connection. Lastly, the buffalo, though

shaped much more like the cow, is a distinct kind by itself, and never mixes with any of the former: it goes twelve months with young, whereas the cow goes but nine—which testifies an aversion to the latter; and, though bred under the same roof or feeding in the same pasture, is always kept separate, and makes a distinct race in all parts of the world. These two kinds are supposed to be the only real varieties in the cow kind, of which naturalists have given so many varieties. With respect to some circumstances mentioned by travellers—such as that of many kinds defending themselves by voiding their dung against their pursuers—this is a practice which they have in common with other timid creatures when pursued, and arises rather from fear than a desire of defence. The musky smell, also, by which some of them have been distinguished, is found common to many of these kinds in a state of nature, and does not properly make the characteristic marks of any. The particular kind of noise, also, which some of them are known to make, which rather resembles grunting than bellowing or lowing, is but a savage variety which many wild animals have, and which they lose when brought into a state of tameness. For these reasons, Mr. Buffon (whom I have followed in this description) is of opinion that the zebu or little African cow, and the grunting or Siberian cow, are but different races of the bison—as the shape of the horns or the length of the hair are never properly characteristic marks of any animal, but are found to vary with climate, food, and cultivation.

In this manner the number of animals of the cow kind, which naturalists have extended to eight or ten sorts, are reduced to two; and as the utmost deference is paid to the opinion of Mr. Buffon in this particular, I have taken him for my guide. Nevertheless, there is an animal of the cow kind which neither he nor any other naturalist that I know of has hitherto described, yet which makes a very distinct class, and may be added as a third species.

This animal was shown some years ago in London, and seemed to unite many of the characteristics of the cow and the hog—having the head, the horns, and the tail of the former, with the bristles, the colour, and the grunting of the latter. It was about the size of an ass, but broader and thicker—the colour resembling that of a hog, and the hair bristly as in that animal. The hair upon the body was thin, as in the hog; and a row of bristles ran along the spine, rather shorter and softer than in the hog kind. The head was rather larger than that of a cow; the teeth entirely resembled those of that animal, and the tongue was rough in like manner. It fed upon hay, and consequently its internal conformation must have resembled that of the cow kind more than the hog, whose food is always chosen of a kind more succulent. The eyes were placed in the head as with the cow, and were much of the same colour; the horns were black and flattish, but bent rather backwards towards the neck, as in the goat kind; the neck was short and thick, and the back rather rising in the middle; it was cloven footed, like the cow, without those hinder claws that are found in the hog kinds. But the greatest variety of all in this extraordinary creature, which was a female, was, that it had but two teats, and consequently in that respect resembled neither of the kinds to which in other circumstances it bore so strong a similitude. Whether this animal was a distinct kind or a monster I will not pretend to say: it was shown under the name of the bonasus; and it was said by the person who showed it to have come from India. But no credit is to be given to interested ignorance; the person only wanted to make the animal appear as extraordinary as possible; and, I believe, would scarcely scruple a lie or two to increase that wonder in us by which he found the means of living.

## CHAP. III.

## OF ANIMALS OF THE SHEEP AND GOAT KIND.

As no two animals are found entirely the same, so it is not to be expected that any two races of animals should exactly correspond in every particular. The goat and the sheep are apparently different in the form of their bodies, in their covering, and in their horns. They may from hence be considered as two different kinds, with regard to all common and domestic purposes. But if we come to examine them closer, and observe their internal conformation, no two animals can be more alike; their feet, their four stomachs, their scent, their appetites, all are entirely the same, and show the similitude between them; but what makes a much stronger connection is, that they propagate with each other. The buck-goat is found to produce with the ewe an animal that in two or three generations returns to the sheep, and seems to retain no marks of its ancient progenitor. The sheep and the goat, therefore, may be considered as belonging to one family; and were the whole races reduced to one of each they would quickly replenish the earth with their kind.

If we examine the sheep and the goat internally, we shall find, as was said, that their conformation is entirely the same; nor is their structure very remote from that of the cow kind, which they resemble in their hoofs and in their chewing the cud. Indeed, all ruminant animals are internally very much alike. The goat, the sheep, and the deer exhibit to the eye of the anatomist the same parts in miniature which the cow or the bison exhibit in the great. But the differences in these animals are nevertheless sufficiently apparent. Nature has obviously marked the distinctions between the cow and the sheep kind by their form and size; and they are also distinguished from those of the deer kind by never shedding their horns. Indeed, the form and figure of these animals, if there were nothing else, would seldom fail of guiding us to the kind; and we might almost upon sight tell which belong to the deer kind and which are degraded into that of the goat. However, the annually shedding the horns in the deer and the permanence in the sheep draws a pretty exact line between the two kinds; so that we may hold to this distinction only, and define the sheep and goat kind as ruminant animals of a smaller size that never shed their horns.

If we consider these harmless and useful animals in one point of view, we shall find that both have been long reclaimed, and brought into a state of domestic servitude. Both seem to require protection from man, and are in some measure pleased with his society. The sheep, indeed, is the more serviceable creature of the two; but the goat has more sensibility and attachment. The attending upon both was once the employment of the wisest and best of men; and those have been ever supposed the happiest times in which these harmless creatures were considered as the chief objects of human attention. In the earliest ages the goat seemed rather the greater favourite; and, indeed, in some countries it continues such to this day among the poor. However, the sheep has long since become the principal object of human care; while the goat is disregarded by the generality of mankind, or become the possession only of the lowest of the people. The sheep, therefore, and its varieties may be considered first; and the goat, with all its kind, will then properly follow.

**THE SHEEP.**—Those animals that take refuge under the protection of man in a few generations become indolent and helpless. Having lost the habit of self-defence, they seem to lose also the instincts of Nature. The sheep, in its present domestic state, is of all animals the most defenceless and inoffensive. With its liberty it seems to have been deprived of its swiftness and cunning;

and what in the ass might rather be called patience in the sheep appears to be stupidity. With no one quality to fit it for self-preservation, it makes vain efforts at all. Without swiftness, it endeavours to fly; and without strength, sometimes offers to oppose. But these feeble attempts rather incite than repress the insults of every enemy; and the dog follows the flock with greater delight upon seeing them fly, and attacks them with more fierceness upon their unsupported attempts at resistance. Indeed, they run together in flocks rather with the hopes of losing their single danger in the crowd than uniting to repress the attack by numbers. The sheep, therefore, were it exposed in its present state to struggle with its natural enemies of the forest, would soon be extirpated. Loaded with a heavy fleece, deprived of the defence of its horns, and rendered heavy, slow, and feeble, it can have no other safety than what it finds from man. This animal is now, therefore, obliged to rely solely upon that art for protection to which it originally owes its degradation.

But we are not to impute to Nature the formation of an animal so utterly unprovided against its enemies and so unfit for defence. The mouflon, which is the sheep in a savage state, is a bold, fleet creature, able to escape from the greater animals by its swiftness, or to oppose the smaller kinds with the arms it has received from Nature. It is by human art alone that the sheep has become the tardy, defenceless creature we find it. Every race of quadrupeds might easily be corrupted by the same allurements by which the sheep has been thus debilitated and depressed. While undisturbed and properly supplied, none are found to set any bounds to their appetite. They all pursue their food while able, and continue to graze, till they often die of disorders occasioned by too much fatness. But it is very different with them in a state of nature: they are in the forest surrounded by dangers and alarmed with unceasing hostilities; they are pursued every hour from one tract of country to another, and spend a greater part of their time in attempts to avoid their enemies. Thus constantly exercised, and continually practising all the arts of defence and escape, the animal at once preserves its life and native independence, together with its swiftness and the slender agility of its form.

The sheep in its servile state seems to be divested of all inclination of its own; and of all animals it appears the most stupid. Every quadruped has a peculiar turn of countenance—a physiognomy, if we may so call it, that generally marks its nature. The sheep seems to have none of those traits that betoken either courage or cunning; its large eyes separated from each other—its ears sticking out on each side—and its narrow nostrils, all testify the extreme simplicity of this creature; and the position of its horns, also, show that Nature designed the sheep rather for flight than combat. It appears a large mass of flesh supported upon four small, straight legs, ill fitted for carrying such a burden; its motions are awkward; it is easily fatigued, and often sinks under the weight of its own corpulency. In proportion as these marks of human transformation are more numerous, the animal becomes more helpless and stupid. Those which live upon a more fertile pasture and grow fat become entirely feeble; those that want horns are found more dull and heavy than the rest; those whose fleeces are longest and finest are most subject to a variety of disorders; and, in short, whatever changes have been wrought in this animal by the industry of man are entirely calculated for human advantage, and not for that of the creature itself. It might require a succession of ages before the sheep could be restored to its primitive state of activity, so as to become a match for its pursuers of the forest.

The goat, which it resembles in so many other respects, is much its superior. The one has its particular attachments, sees danger, and generally tries to escape it; but

the other is timid without a cause, and secure when real danger approaches. Nor is the sheep, when bred up tame in the house and familiarised with its keepers, less obstinately absurd: from being dull and timid it then acquires a degree of pert familiarity—butts with its head, becomes mischievous, and shows itself every way unworthy of being singled out from the rest of the flock. Thus it seems rather formed for slavery than friendship, and framed more for the necessities than the amusements of mankind. There is but one instance in which the sheep shows any attachment to its keeper; and that is seen rather on the continent than among us in Great Britain. What I allude to is, their following the sound of the shepherd's pipe. Before I had seen them trained in this manner I had no conception of those descriptions in the old pastoral poets—of the shepherd leading his flock from one country to another. As I had been used to see these harmless creatures driven before their keepers, I supposed that all the rest was but invention; but in many parts of the Alps, and even some provinces of France, the shepherd and his pipe are still continued with true antique simplicity. The flock is regularly penned every evening to preserve them from the wolf; and the shepherd returns homeward at sunset with his sheep following him, and apparently pleased with the sound of the pipe, which is blown with a reed, and resembles the chanter of the bagpipe. In this manner, in those countries that still continue poor, the Arcadian life is preserved in all its purity; but in countries where a greater inequality of conditions prevail the shepherd is generally some poor wretch who attends a flock from which he is to derive no benefits, and only guards those luxuries which he is not fated to share.

It does not appear from early writers that the sheep was bred in Britain; and it was not till several ages after this animal was cultivated that the woollen manufacture was carried on among us. That valuable branch of business lay for a considerable time in foreign hands; and we were obliged to import the cloth manufactured from our own materials. There were, notwithstanding, many unavailing efforts among our kings to introduce and preserve the manufacture at home. Henry II., by a patent granted to the weavers of London, directed that if any cloth was found made of a mixture of Spanish wool it should be burned by the mayor. Such edicts at length, although but slowly operated towards establishing this trade among us. The Flemings—who at the revival of arts possessed the art of cloth-working in a superior degree—were invited to settle here; and soon afterwards foreign cloth was prohibited from being worn in England. In the time of Queen Elizabeth this manufacture received every encouragement; and many of the inhabitants of the Netherlands being forced, by the tyranny of Spain, to take refuge in this country, they improved us in those arts in which we at present excel the rest of the world. Every art, however, has its rise, its meridian, and its decline: and it is supposed by many that the woollen manufacture has for some time been decaying amongst us. The cloth now made is thought to be much worse than that of some years past, being neither so firm nor so fine, neither so much liked abroad nor so serviceable at home.

No country, however, produces such sheep as England, either with larger fleeces or better adapted for the business of clothing. Those of Spain, indeed, are finer, and we generally require some of their wool to work up with our own; but the weight of a Spanish fleece is no way comparable to that of Lincolnshire or Warwickshire; and in those counties it is no uncommon thing to give a hundred guineas for a ram.

The sheep without horns are counted the best sort, because a great part of the animal's nourishment is supposed to go up into the horns. Sheep like other ruminant animals, want the upper fore-teeth, but have eight in the lower jaw: two of these drop, and are replaced at two

years old; four of them are replaced at three years old; and all at four. The new teeth are easily known from the rest by their freshness and whiteness. There are some breeds, however, in England that never change their teeth at all; these the shepherds call the "leather-mouthed cattle;" and as their teeth are thus longer wearing, they are generally supposed to grow old a year or two before the rest. The sheep brings forth one or two at a time, and sometimes three or four. The first lamb of an ewe is generally pot-bellied, short, and thick, and of less value than those of a second or third production, the third being supposed the best of all. They bear their young five months; and, by being housed, they bring forth at any time of the year.

But this animal in its domestic state is too well known to require a detail of its peculiar habits, or of the arts which have been used to improve the breed. Indeed, in the eye of an observer of Nature every art which tends to render the creature more helpless and useless to itself may be considered rather as an injury than an improvement; and if we are to look for this animal in its noblest state we must seek for it in the African desert, or the extensive plains of Siberia. Among the degenerate descendants of the wild sheep there have been so many changes wrought as entirely to disguise the kind, and often to mislead the observer. The variety is so great that scarce any two countries has its sheep of the same kind; but there is found a manifest difference in all, either in the size, the covering, the shape, or the horns.

The woolly sheep, as it is seen among us, is found only in Europe, and some of the temperate provinces of Asia. When transported into warmer countries, either into Florida or Guinea, it loses its wool, and assumes a covering fitted to the climate, becoming hairy and rough; it there also loses its fertility, and its flesh no longer has the same flavour. In the same manner, in the very cold countries it seems equally helpless and a stranger; it still requires the unceasing attention of mankind for its preservation; and although it is found to subsist as well in Greenland as in Guinea, yet it seems a natural inhabitant of neither.

Of the domestic kinds to be found in the different parts of the world besides our own, which is common in Europe, the first variety is to be seen in Iceland, Muscovy, and the coldest climates of the north. This, which may be called the Iceland sheep, resembles our breed in the form of the body and the tail, but differs in a very extraordinary manner in the number of the horns, being generally found to have four, and sometimes even eight, growing from different parts of the forehead. These are large and formidable; and the animal seems thus fitted by Nature for a state of war: however, it is of the nature of the rest of its kind, being mild, gentle, and timid. Its wool is very different, also, from that of the common sheep, being long, smooth, and hairy. Its colour is of a dark brown; and under its outward coat of hair it has an internal covering that rather resembles fur than wool, being fine, short, and soft.

The second variety to be found in this animal is that of the broad-tailed sheep, so common in Tartary, Arabia, Persia, Barbary, Syria, and Egypt. This sheep is only remarkable for its large and heavy tail, which is often found to weigh from twenty to thirty pounds. It sometimes grows a foot broad, and is obliged to be supported by a small kind of board that goes upon wheels. This tail is not covered underneath with wool like the upper part, but is bare; and the natives, who consider it as a great delicacy, are very careful in attending and preserving it from injury. Mr. Buffon supposes that the fat which falls into the caul in our sheep goes in these to furnish the tail, and that the rest of the body is from thence deprived of fat in proportion. With regard to their fleeces, in the temperate climates they are, as in our own breed, soft and woolly, but in the warmer lati-

trades they are hairy; yet in both they preserve the enormous size of their tails.

The third observable variety is that of the sheep called "*strepcheros*." This animal is a native of the islands of the Archipelago, and only differs from our sheep in having straight horns surrounded with a spiral furrow.

The last variety is that of the Guinea sheep, which is generally found in all the tropical climates both of Africa and the East Indies. They are of a larger size with a rough hairy skin, short horns, and ears hanging down, with a kind of dewlap under the chin. They differ greatly in form from all the rest, and might be considered as animals of another kind were they not known to breed with other sheep. These, of all the domestic kinds, seem to approach the nearest to the state of nature. They are larger, stronger, and swifter than the common race, and consequently better fitted for the precarious forest life. However, they seem to rely, like the rest, on man for support—being entirely of a domestic nature, and subsisting only in the warmer climates.

Such are the varieties of this animal which have been reduced to a state of domestic servitude. These are all capable of producing among each other; all the peculiarities of their form have been made by climate and human cultivation; and none of them seem sufficiently independent to live in a state of savage nature. They are therefore to be considered as a degenerate race formed by the hand of man, and propagated merely for his benefit. At the same time, while man thus cultivates the domestic kinds he drives away and destroys the savage race, which are less beneficial and more headstrong. These, therefore, are to be found in but a very small number, in the most uncultivated countries, where they have been able to subsist by their native swiftness and strength. It is in the more uncultivated parts of Greece, Sardinia, Corsica, and particularly in the deserts of Tartary, that the moufflon is to be found that bears all the marks of being the primitive race, and which has been actually known to breed with the domestic animal.

The moufflon, or musmon, though covered with hair, bears a stronger similitude to the ram than to any other animal; like the ram it has the eyes placed near the horns; and its ears are shorter than those of the goat; it also resembles the ram in its horns, and in all the particular contours of its form. The horns also are alike; they are of a yellow colour; they have three sides, as in the ram, and bend backwards in the same manner behind the ears; the muzzle and inside of the ears are of a whitish colour tinged with yellow; the other parts of the face are of a brownish grey. The general colour of the hair over the body is of a brown, approaching to that of the red deer. The inside of the thighs and belly are of a white tinged with yellow. The form upon the whole seems more made for agility and strength than that of the common sheep; and the moufflon is actually found to live in a savage state, and maintain itself either by force or swiftness, against all the animals that live by rapine. Such is its extreme speed, that many have been inclined rather to rank it among the deer kind than the sheep. But in this they are deceived, as the musmon has a mark that entirely distinguishes it from that species, being known never to shed its horns. In some these are seen to grow to a surprising size—many of them measuring in their convolutions above two ells long. They are of a yellow colour, as was said; but the older the animal grows the darker the horns become: with these they very often maintain very furious battles between each other; and sometimes they are found broken off in such a manner that the small animals of the forest creep into the cavity for shelter. When the musmon is seen standing on the plain his fore-legs are always straight, while his hinder-legs seem bent under him; but in cases of more active necessity this seeming deformity is removed, and he moves with great swiftness

and agility. The female very much resembles the male of this species, but that she is less, and her horns also are never seen to grow to that prodigious size they are of in the wild ram. Such is the sheep in its savage state—a bold, noble, and even beautiful animal; but it is not the most beautiful creatures that are always found most useful to man. Human industry has therefore destroyed its grace to improve its utility.

**THE GOAT, AND ITS NUMEROUS VARIETIES.**—There are some domestic animals that seem as auxiliaries to the more useful sorts, and which, by ceasing to be the first, are considered as nothing. We have seen the services of the ass slighted because they are inferior to those of the horse; and in the same manner the services of the goat are held cheap because the sheep so far exceeds it. Were the horse or the sheep removed from Nature the inferior kinds would then be invaluable, and the same arts would probably be bestowed in perfecting their kinds that the higher order of animals have experienced. But in their present neglected state they vary but little from the wild animals of the same kind; man has left them their primitive habits and forms; and the less they owe to his assiduity the more they receive from Nature.

The goat seems in every respect more fitted for a life of savage liberty than the sheep. It is naturally more lively, and more possessed with animal instinct. It easily attaches itself to man, and seems sensible of his caresses. It is also stronger, swifter, more courageous, and more playful—lively, capricious, and vagrant; it is not easily confined to its flock, but chooses its own pastures, and loves to stray remote from the rest. It chiefly delights in climbing precipices—in going to the very edge of danger; it is often seen suspended upon an eminence hanging over the sea upon a very little base, and even sleeps there in security. Nature has in some measure fitted it for traversing these declivities with ease: the hoof is hollow underneath, with sharp edges, so that it walks as securely on the ridge of a house as on the level ground. It is a hardy animal, and easily sustained; for which reason it is chiefly the property of the poor, who have no pastures with which to supply it. Happily, however, it seems better pleased with the neglected wild than the cultivated fields of Art; it chooses the heathy mountain or the shrubby rock; its favourite food is the tops of the boughs, or the tender bark of young trees; it seems less afraid of immoderate heat, and bears the warm climates better than the sheep. It sleeps exposed to the sun, and seems to enjoy its warmest fervours. Neither is it terrified at the storm or incommoded by the rain: immoderate cold alone seems to affect it, and is said to produce a vertigo, with which this animal is sometimes troubled. The inconsistency of its nature is perceivable in the irregularity of its gait; it goes forward, stops, runs, approaches, flies, merely from caprice, and with no other seeming reason than the extreme vivacity of its disposition.

There are proofs of this animal's being naturally the friend of man; and that the goat seldom resumes its primæval wildness when once reduced into a state of servitude. In the year 1698, an English vessel happening to touch at the islands of Bonavista, two Negroes came and offered the sailors as many goats as they chose to take away. Upon the captain's expressing his astonishment at this offer, the Negroes assured him that there were but twelve persons on the island, and that the goats were multiplied in such a manner as even to become a nuisance; they added, that instead of giving any trouble to catch them, they followed the few inhabitants that were left with a sort of obstinacy, and were importunate with their tameness.

The goat produces but two at a time, and three at the most; but in the warmer climates, although the animal degenerates and grows less, yet it becomes more fruitful,

being generally found to bring forth three, four, and five at a single delivery. The buck is capable of propagating at the age of one year, and the female at seven months; the fruits of this premature generation, however, are weak and defective; and their best breeding time is generally delayed till the age of two years, or at least eighteen months. One buck is sufficient for a hundred and fifty goats. His appetites are excessive; but this ardour brings on a speedy decay, so that he is enervated in four years at most, and even becomes old before he reaches his seventh year. The goat, like the sheep, continues five months with young, and in some places bears twice a year.

The milk of the goat is sweet, nourishing, and medicinal—not so apt to curdle upon the stomach as that of the cow, and therefore preferable to those whose digestion is but weak. The peculiarity of this animal's food gives the milk a flavour different from that either of the cow or the sheep; for as it generally feeds upon shrubby pastures and heathy mountains, there is an agreeable wildness in the taste very pleasing to such as are fond of that aliment. In several parts of Ireland and the Highlands of Scotland the goat makes the chief possession of the inhabitants. On those mountains where no other useful animal could find subsistence, the goat continues to glean a sufficient living, and supplies the hardy natives with what they consider as varied luxury. They lie upon beds made of their skins, which are soft, clean, and wholesome; they live upon their milk, with oat bread; they convert a part of it into butter, and some into cheese; the flesh, indeed, they seldom taste of, as it is a delicacy which they find too expensive; however, the kid is considered, even by the city epicure, as a great rarity; and the flesh of the goat when properly prepared is ranked by some as no way inferior to venison. In this manner, even in the wildest solitudes, the poor find comforts of which the rich do not think it worth their while to dispossess them; in their mountainous retreats, where the landscape presents only a scene of rocks, heaths, and shrubs that speak the wretchedness of the soil, these simple people have their feasts and their pleasures; their faithful flock of goats attends them to these awful solitudes, and furnishes them with all the necessities of life; while their remote situation happily keeps them ignorant of greater luxury.

As these animals are apt to stray from the flock, no man can attend above fifty of them at a time. They are fattened in the same manner as sheep; but, taking every precaution, their flesh is never so good or so sweet in our climate as that of mutton. It is otherwise between the tropics. The mutton there becomes flabby and lean, while the flesh of the goat rather seems to improve; and in some places the latter is cultivated in preference to the former. We therefore find this animal in almost every part of the world, as it seems fitted for the necessities of man in both extremes. Towards the north, where the pasture is coarse and barren, the goat is fitted to find a scanty subsistence; between the tropics, where the heat is excessive, the goat is fitted to bear the climate; and its flesh is found to improve.

One of the most remarkable varieties we find in the goat is that of Natolia. The Natolian goat (or, as Mr. Buffon calls it, the goat of "Angora") has the ears longer than ours, and broader in proportion. The male has horns of about the same length with the goat of Europe, but black, and turned very differently, going out horizontally on each side of the head, and twisted round in the manner of a corkscrew. The horns of the female are shorter, and encircle the ear somewhat like those of the ram. They are of a dazzling white colour, and in all the hair is very long, thick, fine, and glossy—which, indeed, is the case with almost all the animals of Syria. There are a great number of these animals about Angora, where the inhabitants drive a trade with their hair, which is sold either raw or manufactured into

all parts of Europe. Nothing can exceed the beauty of the stuffs which are made from the hair of almost all the animals of that country. These are well known among us by the name of "camblet."

A second variety is the Assyrian goat of Gesner, which is somewhat larger than ours, with ears almost hanging down to the ground, and broad in proportion. The horns, on the contrary, are not above two inches and a half long, black, and bending a little backwards. The hair is of a fox colour, and under the throat there are two excrescences like the gills of a cock. These animals are chiefly kept round Aleppo for the sake of their milk. They are driven through the streets, and their milk is sold to the inhabitants as they pass along.

In the third variety may be reckoned the little goat of America, which is of the size of a kid, but the hair is as long as that of the ordinary breed. The horns, which do not exceed the length of a man's finger, are thick, and bent downwards so close to the head that they almost enter the skin.

There is an animal of this kind at the Cape of Good Hope, called the "blue goat," which may be ranked as the fourth variety. It is in shape like the domestic, but much larger, being nearly of the size of a stag. Its hair is very short, and of a delightful blue; but it loses a great deal of its beauty when dead. It has a very long beard; but the horns are not so long in proportion as in other goats, being turned spirally in the manner of a corkscrew. It has very long legs, but well proportioned; and the flesh is well tasted, but lean. For this reason, in that plentiful country it is chiefly killed on account of its skin. It is a very shy animal, and seldom comes near the Dutch settlements; but they are found in great abundance in the more uncultivated parts of the country. Besides these, they are found in this extensive region of various colours, and many of them are beautifully spotted with red, white, and brown.

In fine, the Juda goat resembles ours in most parts except in size, it being much smaller. This animal is common in Guinea, Angola, and all along the coast of Africa; it is not much larger than the hair, but extremely fat, and its flesh admirably tasted. It is in that country universally preferred to mutton.

These animals seem all of one kind, with very trifling distinctions between them. It is true that they differ in some respects, such as having neither the same colour, hair, ears, nor horns. But it ought to be considered as a rule in natural history, that neither the horns, the colour, fineness, or length of the hair, nor the position of the ears, are to be considered as making an actual distinction in the kinds. These are actual varieties produced by climate and food, which are known to change even in the same animal, and give it a seeming difference of form. When we see the shapes, the inclinations, and the internal conformation of seemingly different creatures nearly the same, and, above all, when we see them producing among each other, we then have no hesitation in pronouncing the species to be unquestionably of the goat kind, with which they are so materially connected.

But although these evidently belong to the goat kind, there are others nearly resembling the goat of whose kindred we cannot be certain. These are such as, being found in a state of nature, have not as yet been sufficiently subjected to human observation. Hence it is impossible to determine with precision to which class they belong—whether they be animals of a particular kind, or merely the goat in its state of savage freedom. Were there but one of these wild animals the inquiry would soon be ended, and we might readily allow it for the parent stock; but in the present case there are two kinds that have almost equal pretensions to this honour, and the claims of which it has been found difficult to determine. The animals in question are the chamois and the ibex. They both bear very near approaches to

+ hare

the goat in figure—have horns that never shed, and at the same time are more different from each other than from the animal in question. From which of these two sources our domestic goat is derived is not easy to settle. Instead, therefore, of entering into the discussion, I will content myself with the result of Mr. Buffon's inquiries. He is of opinion that the ibex is the principal source; that our domestic goat is the immediate descendant; and that the chamois is but a variety from that stock—a sort of collateral branch of the same family. His principal reason for giving the preference to the ibex is its having a more masculine figure, large horns, and a large beard; whereas the chamois wants these marks of primitive strength and wildness. He supposes, therefore, in their original savage state that our goat has taken after the male of the parent stock, and the chamois after the female; and that this has produced a variety in these animals even before they underwent cultivation.

However this be, the two animals in question seem both well fitted for their precarious life, being extremely swift, and capable of running with ease along the ledges of precipices, where even the wolf or the fox, though instigated by hunger, dare not pursue them. They are both natives of the Alps, the Pyrenees, and the mountains of Greece; there they propagate in vast numbers, and continue to exist in spite of the hunter and every beast of prey that is found incessantly to pursue them.

The ibex resembles the goat in the shape of its body, but differs in the horns, which are much larger. They are bent backward, full of knots; and it is generally asserted that there is a knot added every year. There are some of these found, if we may believe Bellonius, at least two yards long. The ibex has a black beard, is of a brown colour, with a thick warm coat of hair. There is a streak of black runs along the top of the back; and the belly and back of the thighs are of a fawn colour.

The chamois, though a wild animal, is very easily tamed, and is found only in rocky and mountainous places. It is about the size of a domestic goat, and resembles one in many respects. It is most agreeably lively, and active beyond expression. The chamois' hair is short like that of the doe; in spring it is of an ash colour, in autumn a dun colour, inclining to black, and in winter of a blackish brown. This animal is found in great plenty in the mountains of Dauphiny, of Piedmont, Savoy, Switzerland, and Germany. They are peaceful, gentle creatures, and live in society with each other. They are found in flocks of from four to four score, and even a hundred, dispersed upon the crags of the mountains. The large males are seen feeding detached from the rest, except in rutting time, when they approach the females, and drive away the young. The time for their coupling is from the beginning of September to the end of October; and they bring forth in April and March. The young keeps with the dam for about five months, and sometimes longer, if the hunters and the wolves do not separate them. It is asserted that they live between twenty and thirty years. Their flesh is good to eat; and they are found to have ten or twelve pounds of suet, which far surpasses that of the goat in hardness and goodness. The chamois has scarce any cry, as most animals are known to have; if it has any, it is a kind of feeble bleat, by which the parent calls its young. But in cases of danger, and when it is to warn the rest of the flock, it uses a hissing noise, which is heard at a great distance—for it is to be observed that this creature is extremely vigilant, and has an eye the quickest and most piercing in Nature. Its smell, also, is not less distinguishing. When it sees its enemy distinctly it stops for a moment; and then, if the person be near, in an instant after it flies off. In the same manner, by its smell it can discover a man at half a league distance, and gives the earliest notice. Upon any alarm, therefore,

or any apprehensions of danger, the chamois begins his hissing note with such force that the rocks and the forests re-echo to the sound. The first hiss continues as long as the time of one inspiration. In the beginning it is very sharp, and deeper towards the close. The animal, having after this first alarm reposed a moment, again looks round, and, perceiving the reality of its fears, continues to hiss by intervals, until it has spread the alarm to a very great distance. During this time it seems in the most violent agitation; it strikes the ground with its fore-foot, and sometimes with both; it bounds from rock to rock; it turns and looks round; it runs to the edge of the precipice; and, still perceiving the enemy, flies with all its speed. The hissing of the male is much louder and sharper than that of the female; it is performed through the nose, and is properly no more than a very strong breath driven violently through a small aperture. The chamois feeds upon the best herbage, and chooses the most delicate parts of the plants—the flower and the tender buds. It is not less delicate with regard to several aromatic herbs which grow upon the sides of the mountains. It drinks but very little while it feeds upon the succulent herbage, and chews the cud in the intervals of feeding. This animal is greatly admired for the beauty of its eyes, which are round and sparkling, and which mark the warmth of its constitution. Its head is furnished with two small horns, of about half a foot long, of a beautiful black, and rising from the forehead almost betwixt the eyes. These, contrary to what they are found in other animals, instead of going backwards or sideways, jet out forward, and bend a little at their extremities backward in a small circle, and end in a very sharp point. The ears are placed in a very elegant manner near the horns; and there are two stripes of black on each side of the face, the rest being of a whitish yellow, which never changes. The horn of this animal is often used as the head of a cane. Those of the female are less, and not so much bent; and some farriers are seen to bleed cattle with them. These animals are so much incommoded by heat that they are never found in summer, except in the caverns or rocks, amidst fragments of unmelted ice, under the shade of high and spreading trees, or of rough and hanging precipices that face the north, and which keep off entirely the rays of the sun. They go to pasture both morning and evening, and seldom during the heat of the day. They run along the rocks with great ease and seeming indifference, and leap from one to another so that no dogs are able to pursue them. There is nothing more extraordinary than to see them climbing and descending precipices that to all other quadrupeds are inaccessible. They always mount or descend in an oblique direction, throw themselves down a rock of thirty feet, and light with great security upon some excrescence or fragment on the side of the precipice, which is just large enough to place their feet upon; in their descent, however, they strike the rock with their feet three or four times to stop the velocity of their motion, and when they have got upon the base below they at once seem fixed and secure. In fact, to see them jump in this manner, they seem rather to have wings than legs; some, indeed, pretend to say that they use their horns in climbing, but this wants confirmation. Certain it is that their legs alone are formed for this arduous employment, the hinder being rather longer than the fore-legs, and bending in such a manner that, when they descend upon them, they break the force of the fall. It is also asserted that when they feed one of them always stands as sentinel, but how far this may be true is questionable: for certain, while they feed there are some of them that keep continually gazing round the rest; but this is practised among all gregarious animals—so that when they see any danger they warn the rest of the herd of its approach. During the rigours of winter the chamois sleeps in the thicker

forests, and feeds upon the shrubs and buds of the pine-tree. It sometimes turns up the snow with its foot to look for herbage, and where it is green makes a delicious repast. The more craggy and uneven the forest the more this animal is pleased with the abode, which thus adds to its security. The hunting the chamois is very laborious and extremely difficult. The most usual way is to hide behind the clefts of the rocks and shoot them. This, however, must be done with great precaution; the sportsman must creep for a vast way upon his belly in silence, and also take advantage of the wind, which if it blow from him they would instantly perceive. When arrived at a proper distance he then advances his piece (which should be rifle-barrelled, and carry but one ball) and tries his fortune among them. Some also pursue this animal as they do the stag, by placing proper persons at all the passages of a glade or valley, and then sending others to rouse the game. Dogs are quite useless in this chase, as they rather alarm than overtake. Nor is it without danger even to the men; for it often happens that when the animal finds itself over-pressed it darts at the hunter with its head, and often tumbles him down the neighbouring precipice. This animal cannot go upon ice when smooth; but if there be the least inequalities on its surface it then bounds along in security, and quickly evades all pursuit.

The skin of the chamois was once famous when tanned or its softness and warmth; at present, however, since the art of tanning has been brought to greater perfection, the leather called "shammoy" is made also from those of the tame goat, the sheep, and the deer. Many medicinal virtues also were said to reside in the blood, fat, gall, and the concretion sometimes found in the stomach of this animal, called the "German bezoar." The fat, mixed with milk, was said to be good in ulcers of the lungs. The gall was said to be useful in strengthening the sight; the stone, which is generally about the size of a walnut, and blackish, was formerly in great request for having the same virtues with oriental bezoar. However, in the present enlightened state of physic, all those medicines are quite out of repute; and although we have the names of several medicines procurable from quadrupeds, yet, except the musk or hartshorn alone, I know of none in any degree of reputation. It is true, the fat, the urine, the beak, and even the dung of various animals may be found efficacious where better remedies are not to be had; but they are far surpassed by many at present in use, whose operations we know, and whose virtues are confirmed by repeated experience.

Such are the quadrupeds that more peculiarly belong to the goat kind. Each of these in all probability can engender and breed with the other; and were the whole race extinguished except any two, these would be sufficient to replenish the world and continue the kind. Nature, however, proceeds in her variations by slow and insensible degrees, and scarce draws a firm, distinguished line between any two neighbouring races of animals whatsoever. Thus it is hard to discover where the sheep ends and the goat begins; and we shall find it still harder to fix precisely the boundaries between the goat kind and the deer. In all transitions from one kind to the other, there are found to be a middle race of animals that seem to partake of the nature of both, and that can precisely be referred to neither. That race of quadrupeds called the "gazelles" are of this kind; they are properly neither goat nor deer, and yet they have many of the marks of both; they make the shade between these two kinds, and fill up the chasm in Nature.

**THE GAZELLES.**—The gazelles, of which there are several kinds, can with propriety be referred neither to the goat nor the deer; and yet they partake of both natures. Like the goat, they have hollow horns that never fall, which is otherwise in the deer. They have a gall-bladder, which is found in the goat and not in the

deer; and, like that animal, they feed rather upon shrubs than grassy pasture. On the other hand, they resemble the roebuck in size and delicacy of form; they have deep pits under the eyes like that animal; they resemble the roebuck in the colour and nature of their hair; they resemble him in the bunches upon their legs, which only differ in being upon the fore-legs in these and on the hind-legs in the other. They seem, therefore, to be of a middle nature between these two kinds, or, to speak with greater truth and precision, they form a distinct kind by themselves.

The distinguishing marks of this tribe of animals, by which they differ both from the goat and the deer, are these:—Their horns are made differently, being annulated or ringed round, at the same time that there are longitudinated depressions running from the bottom to the point. They have bunches of hair upon their fore-legs; they have a streak of black, red, or brown running along the lower part of their sides, and three streaks of whitish hair in the internal side of the ear. These are characters that none of them are without; besides these, there are others which in general they are found to have, and which are more obvious to the beholder. Of all animals in the world, the gazelle has the most beautiful eye, extremely brilliant, and yet so meek, that all the eastern poets compare the eyes of their mistresses to those of this animal. A gazelle-eyed beauty is considered as the highest compliment that a lover can pay; and, indeed, the Greeks themselves thought it no inelegant piece of flattery to resemble the eyes of a beautiful woman to those of a cow. The gazelle for the most part is more delicately and finely limbed than even the roebuck; its hair is as short, but finer and more glossy. Its hinder legs are longer than those before, as in the hare, which gives it great security in ascending or descending steep places. Their swiftness is equal, if not superior, to that of the roe; but as the latter bounds forward, so these run along in an even uninterrupted course. Most of them are brown upon the back, white under the belly, with a black stripe separating those colours between. Their tail is of various lengths, but in all covered with pretty long hair; and their ears are beautiful, well-placed, and terminating in a point. They all have a cloven hoof, like the sheep; they all have permanent horns; and the female has them smaller than the male.

Of these animals Mr. Buffon makes twelve varieties, which, however, is much fewer than what other naturalists have made them. The first is the "gazelle," properly so called, which is of the size of the roebuck, and much resembling it in all the proportions of its body, but entirely differing in the nature and fashion of the horns, which are black and hollow, like those of the ram or the goat, and never fall. The second he calls the "kevel," which is rather less than the former; its eyes seem larger; and its horns, instead of being round, are flattened on the sides, as well in the male as the female. The third he calls the "corin," which greatly resembles the two former, but that it is still less than either. Its horns, also, are smaller in proportion, smoother than those of the other two, and the annular prominences belonging to the kind are scarce discernible, and may be rather called wrinkles than prominences. Some of these animals are often seen streaked like the tiger. These three are supposed to be of the same species. The fourth he calls the "zeiran," the horns only of which he has seen, which, from their size and the description of travellers, he supposes to belong to a larger kind of the gazelle, found in India and Persia under that denomination.

The fifth he calls the "koba," and the sixth the "kob;" these two differ from each other only in size, the former being much larger than the latter. The muzzle of these animals is much longer than those of the ordinary gazelle; the head is differently shaped, and they have no depressions under the eyes. The seventh he calls

after its Egyptian name, the "algazel," which is shaped pretty much like the ordinary gazelle, except that the horns are much longer, being generally three feet from the point to the insertion; whereas, in the common gazelle they are not above a foot; they are, also, smaller and straighter till near the extremities, when they turn short, with a very sharp flexure: they are black and smooth, and the annular prominences are scarcely observable. The eighth is called the "pazan," or by some the "bezoar goat," which greatly resembles the former, except a small variety in their horns; and also with this difference, that as the algazel feeds upon the plains this is only found in the mountains. They are both inhabitants of the same countries and climates, being found in Egypt, Arabia, and Persia. This last is the animal famous for that concretion in the intestines or stomach, called the "oriental bezoar," which was once in such repute all over the world for its medicinal virtues. The word bezoar is supposed to take its name either from the pazan or pazar, which is the animal that produces it; or from a word in the Arabic language, which signifies antidote, or counter-poison. It is a stone of a glazed blackish colour, found in the stomach or the intestines of some animal, and brought over to us from the East Indies. Like all other animal concretions, it is found to have a kind of nucleus, or hard substance within, upon which the external coatings were formed: for, upon being sawed through, it is seen to have layer over layer, as in an onion. This nucleus is of various kinds; sometimes the buds of a shrub, sometimes a piece of stone, and sometimes a marcasite. This stone is from the size of an acorn to that of a pigeon's egg; the larger the stone the more valuable it is held—its price increasing like that of a diamond. There was a time when a stone of four ounces sold in Europe for above two hundred pounds, but at present the price is greatly fallen, and they are in very little esteem. The bezoar is of various colours—sometimes of a blood colour, sometimes of a pale yellow, and of all the shades between these two. It is generally glossy, smooth, and has a fragrant smell, like that of ambergris, probably arising from the aromatic vegetables upon which the animal that produces it feeds. It has been given in vertigoes, epilepsis, palpitations of the heart, cholic, jaundice, and, in those places where the dearness and not the value of medicines is consulted, in almost every disorder incident to man. In all, perhaps, it is equally efficacious, acting only as an absorbent powder, and possessing virtues equal to common chalk or crabs-claws. Judicious physicians have therefore discarded it; and this celebrated medicine is now chiefly consumed in countries where the knowledge of Nature has been but little advanced. When this medicine was in its highest reputation many arts were used to adulterate it; and many countries endeavoured to find out a bezoar of their own. Thus we had occidental bezoar brought from America; German bezoar, which has been mentioned before; cow bezoar, and monkey bezoar. In fact, there is scarce an animal, except of the carnivorous kinds, that does not produce some of these concretions in the stomach, intestines, kidneys, bladder, and even in the heart. To these ignorance may impute virtues that they do not possess—experience has found but few cures wrought by their efficacy; but it is well known that they often prove fatal to the animal that bears them. These concretions are generally found in cows, by their practice of licking off their hair, which gathers in the stomach into the shape of a ball, acquires a surprising degree of hardness, and sometimes a polish like leather. They are often as large as a goose-egg; and, when become too large to pass, block up the passage of the food, and the animal dies. The substance of these balls, however, is different from the bezoar mentioned above—being rather a concretion of hair than of stone. There is a bezoar found in the gall-bladder of a boar, and thence called

"hog bezoar," in great esteem, but perhaps with as little justice as any of the former. In short, as we have already observed, there is scarce an animal or scarce a part of their bodies in which concretions are not formed; and it is more than probable, as Mr. Buffon justly remarks, that the bezoar so much in use formerly was not the production of the pazan, or any one animal only, but that of the whole gazelle kind, who, feeding upon odoriferous herbs and plants, gave this admirable fragrance to the accidental concretions which they were found to produce. As this medicine, however, is but little used at present, our curiosity is much abated as to the cause of its formation. To return, therefore, to the varieties in the gazelle tribe. The ninth is called the "ranger," and is a native of Senegal. This differs somewhat in shape and colour from the rest; but particularly in the shape of its horns, which are straight near to the points, where they crook forward, much in the same manner as in the chamois they crook backward. The tenth variety of the gazelle is the "antelope"—so well known to the English, who have given it the name. It is of the size of the roebuck, and resembles the gazelle in many particulars, but differs in others: it has deeper eye-pits than the former; the horns are also formed differently, being about sixteen inches long, almost touching each other at the bottom, and spreading as they rise, so as at their tips to be sixteen inches asunder. They have the annular prominences of their kind, but not so distinguishable as in the gazelle; however, they have a double flexure, which is very remarkable, and serves to distinguish them from all others of their kind. At the root they have a tuft of hair, which is longer than that of any other part of the body. Like others of the same kind, the antelope is brown on the back and white under the belly; but these colours are not separated by the black streak which is to be found in all the rest of the gazelle kinds. There are different sorts of the animal—some with larger horns than others, and others with less. The one which makes the eleventh variety in the gazelle kind Mr. Buffon calls the "lidme," which has very long horns; and the other, which is the twelfth and last, he calls the "Indian antelope," the horns of which are very small.

To these may be added three or four varieties more, which it is not easy to tell whether to refer to the goat or the gazelle, as they equally resemble both. The first of these is the "bubalus," an animal that seems to partake of the mixed natures of the cow, the goat, and the deer. It resembles the stag in the size and the figure of its body, and particularly in the shape of its legs. But it has permanent horns, like the goat, and made entirely like those of the gazelle kind. It also resembles that animal in its way of living; it differs, however, in the make of its head, being exactly like the cow in the length of its muzzle and in the disposition of the bones of its skull—from which similitude it has taken its name. This animal has a long, narrow head; the eyes are placed very high; the forehead short and narrow; the horns permanent, about a foot long, black, thick, annulated, and the rings of the gazelle kind, very large; its shoulders are very high, and it has a kind of bunch on them, which terminates at the neck; the tail is about a foot long, and tufted with hair at the extremity. The hair of this animal is remarkable in being thicker at the middle than at the root: in all other quadrupeds, except the elk and this, the hair tapers off from the bottom to the point; but in these, each hair seems to swell in the middle like a nine-pin. The bubalus also resembles the elk in size and the colour of its skin; but these are the only similitudes between them: as the one has a large branching head of solid horns that are annually deciduous, the other has black unbranching hollow horns that never fall. The bubalus is common enough in Barbary, and has often been called by the name of the "barbary cow" from which animal

it differs so widely. It partakes pretty much of the nature of the antelope—like that animal having the hair short, the hide black, the ears pointed, and the flesh good for food.

The second anomalous animal of the goat kind Mr. Buffon calls the "condoma." It is supposed to be equal in size to the largest stag, but with hollow horns like those of the goat kind, and with varied flexures like those of the antelope. They are above three feet long, and at their extremities about two feet asunder. All along the back there runs a white list, which ends at the insertion of the tail; another of the same colour crosses this at the bottom of the neck, which it entirely surrounds: there are two more of the same kind running round the body, one behind the fore-legs, and the other running parallel to it before the hinder. The colour of the rest of the body is greyish, except the belly, which is white: it has also a long grey beard; and its legs, though long, are well proportioned.

The third that may be mentioned he calls the "guiba." It resembles the gazelle in every particular, except in the colour of the belly, which, as we have seen, is white in them, but in this is of a deep brown. Its horns, also, are not marked with annular prominences, but are smooth and polished. It is also remarkable for white lists on a brown ground, that are disposed along the animal's body as if it were covered with harness. Like the former, it is a native of Africa.

The "African wild goat" of Grimmus is the fourth. It is of a dark ash-colour; and in the middle of the head is a hairy tuft standing upright; on both sides, between the eyes and the nose, there are very deep cavities greater than those of the other kinds, which contain a yellow oily liquor, which coagulates into a black substance, and has a smell between musk and civit. This being taken away the liquor again runs out, and coagulates as before. These cavities have no communication with the eyes, and consequently this oozing substance can have nothing of the nature of tears.

To this we may add the "chevrotin," or little Guinea deer, which is the least of all cloven-footed quadrupeds, and perhaps the most beautiful; its legs at the smallest part are not much thicker than the shank of a tobacco-pipe; it is about seven inches high, and about twelve from the point of the nose to the insertion of the tail. It is the most delicately shaped in the world, being completely formed like a stag in miniature; except that its horns, when it has any, are more of the gazelle kind, being hollow and annulated in the same manner. It has two canine teeth in the upper jaw; in which respect it differs from all other animals of the goat or deer kind, and thus makes a species entirely distinct by itself. This wonderful animal's colour is not less pleasing—the hair, which is short and glossy, being in some of a beautiful yellow, except on the neck and belly, which is white. They are natives of India, Guinea, and the warm climates between the tropics, and are found in great plenty. But though they are amazingly swift for their size, yet the Negroes often overtake them in the pursuit, and knock them down with their sticks. They may be easily tamed, and then they become familiar and pleasing; but they are of such delicate constitutions that they can bear no climate but the hottest; and they always perish with the rigours of ours when they are brought over. The male in Guinea has horns—the female is without any; as are all the kinds of this animal to be found either in Java or Ceylon, where they chiefly abound.

Such is the list of the gazelles—all which pretty nearly resemble the deer in form and delicacy of shape, but have the horns hollow, single, and permanent like those of the goat. They properly fill up, as has been already observed, the interval between these two kinds of animals; so that it is difficult to tell where the goat ends and the deer may be said to begin. If we compare the gazelles with each other we shall find but very slight

distinctions between them. The turn or the magnitude of the horns, the different spots on the skin, or a difference of size in each, are chiefly the marks by which their varieties are to be known; but their way of living, their nature, and their peculiar swiftness, all come under one description.

The gazelles are in general inhabitants of the warmer climates, and contribute, among other embellishments, to add beauty to those forests that are for ever green. They are often seen feeding in herds on the sides of the mountain, or in the shade of the woods, and fly altogether on the slightest approach of danger. They bound with such swiftness and are so very shy, that dogs or men vainly attempt to pursue them. They traverse those precipices with ease and safety which to every quadruped else are quite impracticable; nor can any animals but of the winged kind overtake them. Accordingly, in all those countries where they are chiefly found they are pursued by falcons; and this admirable manner of hunting makes one of the principal amusements of the upper ranks of people all over the East. The Arabians, Persians, and Turks breed up for this purpose that kind of hawk called the "falcon gentle," with which, when properly trained, they go forth upon horseback among the forests and the mountains, the falcon perching upon the hand of the hunter. Their expedition is conducted with profound silence; their dogs are taught to hang behind; while the men, on the fleetest coursers, look round for the game. Whenever they spy a gazelle at the proper distance then they point the falcon to its object, and encourage it to pursue. The falcon, with the swiftness of an arrow, flies to the animal—which, knowing its danger, endeavours, but too late, to escape. The falcon, soon coming up with its prey, fixes its talons, one into the animal's cheek and the other into its throat, and deeply wounds it. On the other hand, the gazelle attempts to escape, but is generally wounded too deep to run far. The falcon clings with the utmost perseverance, nor ever leaves its prey till it falls; upon which the hunters from behind approaching they take up both, and reward the falcon with the blood of the spoil. They also teach the young ones by applying them to the dead animal's throat, and accustoming them betimes to fix upon that particular part; for if it should happen that the falcon fixed upon any other part of the gazelle, either its back or its haunches, the animal would easily escape among the mountains, and the hunter would also lose his falcon. They sometimes hunt this animal with the ounce. This carnivorous and fierce creature, being domesticated, generally sits on horseback behind the hunter, and remains there with the utmost composure until the gazelle is shown; it is then that it exerts all its arts and fierceness; it does not at once fly at its prey, but approaches slyly, turning and winding about until it comes within the proper distance, when all at once it bounds upon the heedless animal, and instantly kills it and sucks its blood. If, on the other hand, it misses its aim, it remains in its place without attempting to pursue any further, but seems ashamed of its own inability.

There is still another way of taking the gazelle, which seems not so certain nor so amusing as either of the former. A tame gazelle is bred up for this purpose, who is taught to join those of its kind wherever it perceives them. When the hunter, therefore, sees a herd of these together, he fixes a noose round the horns of the tame gazelle in such a manner that if the rest but touch it they are entangled; and, thus prepared, he sends his gazelle among the rest. The tame animal no sooner approaches but the males of the herd instantly sally forth to oppose him, and in butting with their horns are caught in the noose. In this, both struggling for some time, at length fall together to the ground; when the hunter coming up he disengages the one and kills the other. Upon the whole, however, these animals, what

ever be the arts used to pursue them, are very difficult to be taken. As they are continually subject to alarms from carnivorous beasts or from man, they keep chiefly in the most solitary and inaccessible places, and find their only protection from situations of the greatest danger.

#### CHAP. IV.

##### OF THE MUSK ANIMAL.

The more we search into Nature the more we shall find how little she is known; and we shall more than once have occasion to find that protracted inquiry is more apt to teach us modesty than to produce information. Although the number and nature of quadrupeds at first glance seems very little known; yet, when we come to examine closer, we find some with which we are only partially acquainted, and others that are quite unknown. There is scarce a cabinet of the curious but what has the spoils of animals or the horns or the hoofs of quadrupeds which do not come within former descriptions. There is scarce a person whose trade is to dress or improve furs but knows several creatures by their skins which no naturalist has hitherto had notice of. But of all quadrupeds, there is none so justly deserving the reproach of natural historians as that which bears the musk. This perfume—so well known to the elegant and so very useful in the hands of the physician; a medicine that has for more than a century been imported from the East in great quantities, and during all that time has been improving in its reputation—is, nevertheless, so little understood, that it remains a doubt whether the animal that produces it be a hog, an ox, a goat, or a deer. When an animal with which we are so nearly connected is so utterly unknown, how little must we know of many that are more remote and unserviceable! Yet naturalists proceed in the same train, enlarging their catalogues and their names without endeavouring to find out the nature and fix the precise history of those with which we are but very partially acquainted. It is the spirit of the scholars of the present age to be fonder of increasing the bulk of our knowledge than its utility—of extending their conquests rather than improving their empire.

The musk which comes to Europe is brought over in small bags about the size of a pigeon's egg, which, when cut open, appear to contain a kind of dusky reddish substance like coagulated blood, and which in large quantities has a very strong smell, but when mixed and diffused becomes a very agreeable perfume. Indeed, no substance now known in the world has a stronger or more permanent smell. A grain of musk perfumes a whole room; and its odour continues for some days without diminution. But in a larger quantity it continues for years together, and seems scarce wasted in its weight, although it has filled the atmosphere to a great distance with its parts. It is particularly used in medicine in nervous and hysteric disorders, and is found in such cases to be the most powerful remedy now in use; however, the animal that furnishes this admirable medicine has been variously described, and is known but very imperfectly.

The description given of this animal by Grew is as follows:—"The musk animal is properly neither of the goat nor the deer kind, for it has no horns, and it is uncertain whether it ruminates or not; however, it wants the fore-teeth in the upper jaw in the same manner as in ruminating animals: but at the same time it has tusks like those of a hog. It is three feet six inches in length from the head to the tail; and the head is above half a foot long. The fore-part of the head is like that of a greyhound; and the ears are three inches long, and

erect, like those of a rabbit; but the tail is not above two inches. It is cloven-footed, like beasts of the goat kind; the hair on the head and legs is half an inch long, on the belly an inch and a half, and on the back and buttocks three inches, and proportionably thicker than in any other animal. It is brown and white alternately from the root to the point; on the head and thighs it is brown, but under the belly and tail white, and a little curled, especially on the back and belly. On each side of the lower jaw under the corners of the mouth there is a tuft of thick hair, which is short and hard, and about three quarters of an inch long. The hair in general of this animal is remarkable for its softness and fine texture; but what distinguishes it particularly are the tusks, which are an inch and a half long, and turn back in the form of a hook; and more particularly the bag which contains the musk, which is three inches long, two broad, and stands out from the belly an inch and a half. It is a very fearful animal, and therefore it has long ears; and the sense of hearing is so quick that it can discover an enemy at a great distance."

After so circumstantial a description of this animal its nature is but very little known; nor has any anatomist yet examined its internal structure, or been able to inform us whether it be a ruminant animal or one of the hog kind; how the musk is formed, or whether those bags in which it comes to us be really belonging to the animal or are only the sophistications of the venders. Indeed, when we consider the immense quantities of this substance which are consumed in Europe alone, not to mention the East, where it is in still greater repute than here, we can hardly suppose that any one animal can furnish the supply—and particularly when it must be killed before the bag can be obtained. We are told, it is true, that the musk is often deposited by the animal upon trees and stones, against which it rubs itself when the quantity becomes uneasy; but it is not in that form which we receive it, but always in what seems to be its own natural bladder. Of these, Taverner brought home near two thousand in one year; and, as the animal is wild, so many must during that space have been hunted and taken. But as the creature is represented very shy, and as it is found but in some particular provinces of the East, the wonder is how its bag should be so cheap, and furnished in such great plenty. The bag in common does not cost (if I do not forget) above a crown by retail, and yet this is supposed the only one belonging to the animal, and for the obtaining of which it must have been hunted and killed. The only way of solving this difficulty is to suppose that these bags are in a great measure counterfeit, taken from some other animal, or from some part of the same, filled with its blood and a very little of the perfume, but sufficient to impregnate the rest with a strong and permanent odour. It comes to us from different parts of the East—from China, Tonquin, Bengal, and often from Muscovy. That of Thibet is reckoned the best, and sells for fourteen shillings an ounce; that of Muscovy the worst, and sells but for three—the odour of this, though very strong at first, being quickly found to evaporate. Musk was some years ago in the highest request as a perfume, and but little regarded as a medicine; but at present its reputation is totally changed; and having been found of great benefit in physic, it is but little regarded for purposes of elegance. It is thus that things which become necessary cease to continue pleasing, and the consciousness of their use destroys their power of administering delight.

## CHAP. V.

## ANIMALS OF THE DEER KIND.

If we compare the stag and the bull, as to shape and form, no two animals can be more unlike; and yet, if we examine their internal structure we shall find a striking similitude between them. Indeed, their differences, except to a nice observer, will scarcely be perceivable. All of the deer kind want the gall-bladder; their kidneys are formed differently; their spleen is also proportionably larger; their tail is shorter; and their horns, which are solid, are renewed every year. Such are the slight internal discriminations between two animals, one of which is among the swiftest and the other the heaviest of the brute creation.

The stag is one of those innocent and peaceable animals that seems made to embellish the forest and animate the solitudes of Nature. The easy elegance of his form—the lightness of his motions—those large branches that seem made rather for the ornament of his head than his defence—the size, the strength, and the swiftness of this beautiful creature—all sufficiently rank him among the first of quadrupeds, among the most noted objects of human curiosity.

The stag, or hart, whose female is called a "hind," and the young a "calf," differs in size and horns from a fallow-deer. He is much larger, and his horns are round; whereas in the fallow kind they are broad and palmated. By these the animal's age is known. The first year the stag has no horns, but a horny excrescence, which is short, rough, and covered with a thin, hairy skin. The next year the horns are single and straight; the third year they have two antlers, three the fourth, four the fifth, and five the sixth; this number is not always certain, for sometimes there are more and often less. When arrived at the sixth year the antlers do not always increase; and although the number may amount to six or seven on each side, yet the animal's age is estimated rather from the size of the antlers and the thickness of the branch that sustains them than from their variety. These horns, large as they seem, are, notwithstanding, shed every year, and new ones come in their place. The old horns are of a firm, solid texture, and usually employed in making handles for knives and other domestic utensils: but while young, nothing can be more soft and tender; and the animal, as if conscious of his own imbecility, at those times, instantly upon shedding his former horns, retires from the rest of his fellows, and hides himself in solitudes and thickets, never venturing out to pasture except by night. During this time, which most usually happens in the spring, the new horns are very painful, and have a quick sensibility of any external impression. The flies, also, are extremely troublesome to him. When the old horn is fallen off the new does not begin immediately to appear; but the bones of the skull are seen covered only with a transparent periosteum of skin, which, as anatomists teach us, covers the bones of all animals. After a short time, however, this skin begins to swell, and to form a soft tumour which contains a great deal of blood, and which begins to be covered with a downy substance that has the feel of velvet, and appears nearly of the same colour with the rest of the animal's hair. This tumour every day buds forward from the point like the graft of a tree, and, rising by degrees from the head, shoots out the antlers on either side, so that in a few days, in proportion as the animal is in condition, the whole head is completed. However, as was said above, in the beginning its consistence is very soft, and has a sort of bark, which is no more than a continuation of an integument of the skull. It is velveted and downy, and everywhere furnished with blood-vessels that supply the growing horns with nourishment. As they creep along the sides of the branches the print

is marked over the whole surface—and the larger the blood-vessels the deeper these marks are found to be. From hence arises the inequality of the surface of the deer's horns—which, as we see, are furrowed all along the sides, the impressions diminishing towards the point, where the substance is as smooth and as solid as ivory. But it ought to be observed, that this substance of which the horns are composed begins to harden at the bottom while the upper part remains soft, and still continues growing; from whence it appears that the horns grow differently in deer from those of sheep or cows—in which they are always seen to increase from the bottom. However, when the whole head has received its full growth the extremities then begin to acquire their solidity; the velvet covering or bark, with its blood-vessels, dry up, and then begin to fall; and this the animal hastens by rubbing its antlers against every tree it meets. In this manner, the whole external surface being stripped off by degrees, at length the whole head acquires its complete hardness, expansion, and beauty.

It would be a vain task to inquire into the cause of the animal production of these horns; it is sufficient to observe, that if a stag be castrated when its horns are fallen off they will never grow again; and on the contrary, if the same operation is performed when they are on, they will never fall off. If only one of his testicles is taken out he will want the horn on that side; if one of the testicles only be tied up he will want the horn on the opposite side. The increase of their provision also tends to facilitate the growth and the expansion of the horns; and Mr. Buffon thinks it possible to retard their growth entirely by greatly retrenching their food. As a proof of this, nothing can be more obvious than the difference between a stag bred in fertile pastures and undisturbed by the hunter, and one often pursued and ill nourished. The former has his head expanded, his antlers numerous, and the branches thick; the latter has but few antlers, the traces of the blood-vessels upon them are but slight, and the expansion but little. The beauty and size of their horns, therefore, mark their strength and their vigour—such of them as are sickly or have been wounded never shooting out that magnificent profusion so much admired in this animal. Thus the horns may in every respect be compared to a vegetable substance grafted upon the head of an animal. Like a vegetable, they grow from the extremities; like a vegetable, they are for a while covered with a bark that nourishes them; like a vegetable, they have their annual production and decay; and a strong imagination might suppose that the leafy productions on which the animal feeds go once more to vegetate in his horns.

The stag is usually twelve months old before the horns begin to appear, and then a single branch is all that is seen for the ensuing year. About the beginning of spring all of this kind are seen to shed their horns, which fall off of themselves; though sometimes the animal assists the efforts of Nature by rubbing them against a tree. It seldom happens that the branches on both sides fall off at the same time, there often being two or three days between the dropping of the one and the other. The old stags usually shed their horns first, which generally happens towards the latter end of February or the beginning of March. Those of the second head—namely, such as are between five and six years old—shed their horns about the middle or latter end of March; those still younger, in the month of April; and the youngest of all not till the middle or the latter end of May; they generally shed them in pools of water, whither they retire from the heat; and this has given rise to the opinion of their always hiding their horns. These rules, though true in general, are yet subject to many variations; and it is universally known that a severe winter retards the shedding of the horns. The horns of the stag generally increase in thickness and in height from the second year of its age to the

eighth. In this state of perfection they continue during the vigour of life; but as the animal grows old the horns feel the impressions of age, and shrink like the rest of the body. No branch bears more than twenty or twenty-two antlers, even in the highest state of vigour; and the number is subject to great variety; for it happens that the stag at one year has either less or more than the year preceding, in proportion to the goodness of his pasture or the continuance of his security, as these animals seldom thrive when often roused by the hunters. The horns are also found to partake of the nature of the soil; in the more fertile pastures they are large and tender; on the contrary, in the barren soil they are hard, stunted, and brittle. As soon as the stags have shed their horns they separate from each other, and seek the plainer parts of the country, remote from every other animal, which they are utterly unable to oppose. They then walk with their heads stooping down, to keep their horns from striking against the branches of the trees above. In this state of imbecility they continue near three months before their heads have acquired their full growth and solidity; and then, by rubbing them against the branches of every thicket, they at length clear them of the skin which had contributed to their growth and nourishment. It is said by some that the horn takes the colour of the sap of the tree against which it is rubbed; and that some thus become red when rubbed against the heath, and others brown by rubbing against the oak; this, however, is a mistake, since stags kept in parks where there are no trees have a variety in the colour of their horns, which can be ascribed to nothing but Nature. A short time after they have furnished their horns they begin to feel the impressions of the rut, or the desire of copulation. The old ones are the most forward; and about the end of August or the beginning of September they quit their thickets, and return to the mountain in order to seek the hind, to whom they call with a loud, tremulous note. At this time their neck is swollen; they appear bold and furious—fly from country to country—strike with their horns against the trees and other obstacles, and continue restless and fierce until they have found the female, who at first flies from them, but is at last overtaken and subdued. When two stags contend for the same female, how timorous soever they may appear at other times, they then seem agitated with an uncommon degree of ardour. They paw the earth, menace each other with their horns, bellow with all their force, and, striking in a desperate manner against each other, seem determined upon death or victory. This combat continues till one of them is defeated or flies; and it often happens that the victor is obliged to fight several of these battles before he remains undisputed master of the field. The old ones are generally the conquerors on these occasions, as they have more strength and greater courage; and these are also preferred by the hind to the young ones, as the latter are more feeble and less ardent. However, they are all equally inconstant, keeping to the female but a few days, and then seeking out for another—not to be enjoyed, perhaps, without a repetition of their former danger.

In this manner the stag continues to range from one to the other for about three weeks—the time the rut continues; during which he scarce eats, sleeps, or rests, but continues to pursue, to combat, and to enjoy. At the end of this period of madness—for such in this animal it seems to be—the creature that was before fat, sleek, and glossy becomes lean, feeble, and timid. He then retires from the herd to seek plenty and repose; he frequents the side of the forest, and chooses the most nourishing pastures, remaining there till his strength is renewed. Thus is his whole life passed in the alternations of plenty and want, of corpulence and inanition, of health and sickness, without having his constitution much affected by the violence of the change. As he is

above five years coming to perfection, he lives about forty years; and it is a general rule, that every animal lives about seven or eight times the number of years which it continues to grow. What, therefore, is reported concerning the life of this animal has arisen from the credulity of ignorance; some say that a stag having been taken in France, with a collar on which were written these words, "Cæsar hoc me donavit," this was interpreted of Julius Cæsar; but it is not considered that Cæsar is a general name for kings, and that one of the emperors of Germany, who are always styled Cæsars, might have ordered the inscription.

This animal may differ in the term of his life according to the goodness of his pasture or the undisturbed repose he happens to enjoy. These are advantages that influence not only his age but his size and vigour. The stags of the plains, the valleys, and the little hills which abound in corn and pasture, are much more corpulent and much taller than such as are bred on the rocky waste or the heathy mountain. The latter are low, small, and meagre, incapable of going so swift as the former, although they are found to hold out much longer. They are also more artful in evading the hunters; their horns are generally black and short, while those of the lowland stags are reddish and flourishing; so that the animal seems to increase in beauty and stature in proportion to the goodness of the pasture which he enjoys in security.

The usual colour of the stag in England was red; nevertheless, the greater number in other countries are brown. There are some few that are white; but these seem to have obtained this colour in a former state of domestic tameness. Of all the animals that are natives of this climate, there are none that have such a beautiful eye as the stag; it is sparkling, soft, and sensible. His senses of smelling and hearing are in no less perfection. When he is in the least alarmed, he lifts the head and erects the ears, standing for a few minutes as if in a listening posture. Whenever he ventures upon some unknown ground, or quits his native covering, he first stops at the skirt of the plain to examine all around; he next turns against the wind to examine by the smell if there be any enemy approaching. If a person should happen to whistle or call out at a distance, the stag is seen to stop short in a slow measured pace, and gazes upon the stranger with a kind of awkward admiration: if the cunning animal perceives neither dogs nor fire-arms preparing against him, he goes forward, quite unconcerned, and slowly proceeds without offering to fly. Man is not the enemy he is most afraid of; on the contrary, he seems to be delighted with the sound of a shepherd's pipe; and the hunters sometimes make use of that instrument to allure the poor animal to his destruction.

The stag eats slowly, and is very delicate in the choice of his pasture. When he has eaten a sufficiency, he then retires to the covert of some thicket to chew the cud in security. His rumination, however, seems performed with much greater difficulty than with the cow or sheep; for the grass is not returned from the first stomach without much straining and a kind of hiccup, which is easily perceived during the whole time it continues. This may proceed from the greater length of the neck and the narrowness of the passage, all those of the cow and the sheep kind having it much wider.

This animal's voice is much stronger, louder, and more tremulous in proportion as he advances in age; in the time of rut it is even terrible. At that season he seems so transported with passion that nothing obstructs his fury; and, when at bay, he keeps the dogs off with great intrepidity. Some years ago, William, Duke of Cumberland, caused a tiger and a stag to be enclosed in the same area, and the stag made so bold a defence that the tiger was at last obliged to fly. The stag seldom drinks in the winter, and still less in the spring, while the plants

are tender and covered over with dew. It is in the heat of summer and during the time of rut that he is seen constantly frequenting the side of rivers and lakes, as well to slake his thirst as to cool his ardour. He swims with great ease and strength, and best at those times when he is fattest, his fat keeping him buoyant, like oil upon the surface of the water. During the time of rut he even ventures out to sea, and swims from one island to another, although there may be some leagues distance between them.

The cry of the hind or female is not so loud as that of the male, and is never excited but by apprehension for herself or her young. It need scarce be mentioned that she has no horns, or that she is more feeble and unfit for hunting than the male. When once they have conceived they separate from the male, and then they both herd apart. The time of gestation continues from eight to nine months, and they generally produce but one at a time. Their usual season for bringing forth is about the month of May or the beginning of June, during which time they take great care to hide their young in the most obscure thickets. Nor is this precaution without reason, since almost every creature is then a formidable enemy. The eagle, the falcon, the osprey, the wolf, the dog, and all the rapacious family of the cat kind, are in continual employment to find out her retreat. But what is more unnatural still, the stag himself is a professed enemy, and the hind is obliged to use all her arts to conceal her young from him as from the most dangerous of all her pursuers. At this season, therefore, the courage of the male seems transferred to the female: she defends her young against her less formidable opponents by force; and, when pursued by the hunter, she ever offers herself to mislead him from the principal objects of her concern. She flies before the hounds for half the day, and then returns to her young, whose life she has thus preserved at the hazard of her own. The "calf" for so the young of this animal is called, never quits the dam during the whole summer; and in winter the hind and all the males under a year old keep together and assemble in herds, which are more numerous in proportion as the season is more severe. In the spring they separate—the hind to bring forth, while none but the year olds remain together. These animals are, however, in general fond of herding and grazing in company; it is danger or necessity alone that separates them.

The dangers they have to fear from other animals are nothing when compared to those from man. The men of every age and nation have made the chase of the stag one of their most favourite pursuits; and those who first hunted from necessity have continued it for amusement. In our own country, in particular, hunting was ever esteemed as one of the principal diversions of the great. At first, indeed, the beasts of chase had the whole island for their range, and knew no other limits than those of the ocean.

The Roman jurisprudence, which was formed on the manners of the first ages, established it as a law that, as the natural right of things that have no master belongs to the first possessor, wild beasts, birds, and fishes are the property of whosoever should first take them. But the northern barbarians, who overran the Roman empire, bringing with them the strongest relish for this amusement, and being now possessed of more easy means of subsistence from the lands they had conquered, their chiefs and leaders began to appropriate the right of hunting, and instead of a natural right to make it a royal one. When the Saxon kings, therefore, had established themselves into a heptarchy, the chases were reserved by each sovereign for his own particular amusement. Hunting and war in those uncivilised ages were the only enjoyment of the great. Their active but uncultivated minds were susceptible of no pleasures but those of a violent kind, such as gave exercise to their bodies.

and prevented the trouble of thinking. But as the Saxon kings only appropriated those lands to the business of the chase which were unoccupied before, so no one received any injury. But it was otherwise when the Norman kings were settled upon the throne. The passion for hunting was then carried to excess, and every civil right was involved in general ruin. This ardour for hunting was stronger than the consideration of religion even in a superstitious age. The village communities, nay, even the most sacred edifices, were thrown down, and all turned into one vast waste, to make room for animals the objects of a lawless tyrant's pleasure. Sanguinary laws were enacted to preserve the game: in the reigns of William Rufus and Henry I. it was less criminal to destroy a human being than a beast of chase. Thus it continued while the Norman line filled the throne; but when the Saxon line was restored under Henry II. the rigours of the forest laws were softened. The barons, also, for a long time imitated the encroachments as well as the amusements of the monarch; but when property became more equally divided by the introduction of arts and industry, these extensive hunting-grounds became more limited; and as tillage and husbandry increased, the beasts of chase were obliged to give way to others more useful to the community. Those vast tracts of land, before dedicated to hunting, were then contracted; and in proportion as the useful arts gained ground they protected and encouraged the labours of the industrious, and repressed the licentiousness of the sportsman. It is, therefore, among the subjects of a despotic government only that these laws remain in full force; where large wastes lie uncultivated for the purposes of hunting; where the husbandman can find no protection from the invasion of his lord, or the continual depredations of those animals which he makes the objects of his pleasure.

In the present cultivated state of this country, therefore, the stag is unknown in its wild natural state; and such of them as remain among us are kept, under the name of "red deer," in parks among the fallow deer. But they are become less common than formerly—its excessive viciousness during the rutting season and the badness of its flesh inducing most people to part with the species. The few that still remain wild are to be found on the moors that border on Cornwall and Devonshire, and in Ireland, on most of the large mountains of that country.

In England, the hunting the stag and the buck are performed in the same manner; the animal is driven from some gentleman's park, and then hunted through the open country. But those who pursue the wild animal have a much higher object, as well as a greater variety in the chase. To let loose a creature that was already in our possession in order to catch it again is, in my opinion, but a poor pursuit, as the reward when obtained is only what we before had given away. But to pursue an animal that owns no proprietor, and which he that first seizes may be said to possess, has something in it that seems at least more rational; this rewards the hunter for his toil, and seems to repay his industry. Besides, the superior strength and swiftness of the wild animal prolongs the amusement; it is possessed of more various arts to escape the hunter, and leads him to precipices where the danger ennobles the chase. In pursuing the animal let loose from a park, as it is unused to danger, it is but little versed in the stratagems of escape; the hunter follows as sure of overcoming, and feels none of those alternations of hope and fear which arise from the uncertainty of success. But it is otherwise with the mountain stag: having spent his whole life in a state of continual apprehension—having frequently been followed and as frequently escaped, he knows every trick to mislead, to confound, or intimidate his pursuers, to stimulate their ardour, and enhance their success.

Those who hunt this animal have their peculiar terms

for the different objects of their pursuit. The professors in every art take a pleasure in thus employing a language known only to themselves, and thus accumulate words which to the ignorant have the appearance of knowledge. In this manner, the stag is called the first year, a calf, or hind calf; the second year, a knobber; the third, a brook; the fourth, a staggard; the fifth, a stag; the sixth, a hart. The female is called the hind; the first year she is a calf; the second, a hearse; the third, a hind. This animal is said to harbour in the place where it resides. When he cries, he is said to bell; the print of his hoof is called the slot; his tail is called the single; his excrement the fewmet; his horns are called his head; when simple, the first year, they are called brooches; the third year, spears; the fourth year, that part which bears the antlers is called the beam, and the little impressions upon its surface glitter; those which rise from the crust of the beam are called pearls. The antlers, also, have distinct names: the first that branches off is called the antler; the second, the sur-antler; all the rest which grow afterwards, till you come to the top, which is called the crown, are called royal antlers. The little buds about the tops are called crooches. The impression on the place where the stag has lain is called the layer. If it be in covert or thicket, leaving marks whereby his bulk may be guessed, it is called an entry. When they cast their heads they are said to mew. When they rub their heads against trees to bring off the peel of their horns they are said to fray. When a stag hard-hunted takes to swimming in the water he is said to go sail; when he turns his head against the hounds he is said to bay; and when the hounds pursue upon the scent until they have unharboured the stag they are said to draw on the slot.

Such are but a few of the many terms used by hunters in pursuing the stag, most of which are now laid aside, or in use only among gamekeepers. The chase, however, is continued in many parts of the country where the red deer is preserved, and still makes amusement for such as have not found out more liberal entertainments. In those few places where the animal is perfectly wild the amusement, as was said above, is superior. The first great care of the hunter when he leads out his hounds to the mountain side, where the deer are generally known to harbour, is to make choice of a proper stag to pursue. His ambition is to unharbour, the largest and the boldest of the whole herd; and for this purpose he examines the track, if there be any, which if he finds long and large, he concludes that it must have belonged to a stag and not a hind, the print of whose foot is rounder. Those marks, also, which he leaves on trees by the rubbing of his horns show his size, and point him out as the proper object of pursuit. Now, to seek out a stag in his haunt, it is to be observed that he changes his manner of feeding every month. From the conclusion of rutting-time, which is November, he feeds in heaths and broomy places. In December they herd together, and withdraw into the strength of the forests to shelter themselves from the severer weather, feeding on holm, elder trees, and brambles. The three following months they leave herding, but keep four or five in a company, and venture out to the corners of the forest, where they feed on winter pasture, sometimes making their incursions into the neighbouring corn-fields, to feed upon the tender shoots which peep above ground. In April and May they rest in thickets and shady places, and seldom venture forth unless roused by approaching danger. In September and October their annual ardour returns; and then they leave the thickets, boldly facing every danger, without any certain place for food or harbour. When, by a knowledge of these circumstances, the hunter has found out the residence and the quality of his game, his next care is to uncouple and cast off his hounds in the pursuit: these no sooner perceive the timorous animal that flies before them but they altogether open in full cry, pursuing rather by the scent

than the view, encouraging each other to continue the chase, and tracing the flying animal with the most amazing sagacity. The hunters, also, are not less ardent in their speed on horseback, cheering up the dogs, and directing them where to pursue. On the other hand, the stag when unharboured flies at first with the swiftness of the wind, leaving his pursuers several miles in the rear; and at length having gained his former coverts, and no longer hearing the cries of the dogs and men that he had just left behind, he stops, gazes round him, and seems to recover his natural tranquillity. But this calm is of short duration, for his inveterate pursuers slowly and securely trace him along, and he once more hears the approaching destruction from behind. He again, therefore, renews his efforts to escape, and again leaves his pursuers at almost the former distance; but this second effort makes him more feeble than before, and when they come up a second time he is unable to outstrip them with equal velocity. The poor animal now, therefore, is obliged to have recourse to all his little arts of escape, which sometimes, though but seldom, avail him. In proportion as his strength fails him the ardour of his pursuers is inflamed; he tracks more heavily on the ground, and this, increasing the strength of the scent, redoubles the cries of the hounds and enforces their speed. It is then that the stag seeks for refuge among the herd, and tries every artifice to put off some other head for his own. Sometimes he will send forth some little deer in his stead, in the mean time lying close himself that the hounds may overshoot him. He will break into one thicket after another to find deer, arousing them, gathering them together, and endeavouring to put them upon the tracks he has made. His old companions, however, with a true spirit of ingratitude, now all forsake and shun him with the most watchful industry, leaving the unhappy creature to take his fate by himself. Thus abandoned of his fellows, he again tries other arts by doubling and crossing in some hard beaten highway, where the scent is least perceivable. He now also runs against the wind, not only to cool himself, but the better to hear the voice, and judge of the distance of his implacable pursuers. It is now easily perceivable how sorely he is pressed by his manner of running, which, from the bounding easy pace with which he began, is converted into a stiff and short manner of going; his mouth, also, is black and dry, wit out any foam on it; his tongue hangs out; and the tears, as some say, are seen starting from his eyes. His last refuge, when every other method of safety has failed him, is to take the water, and to attempt an escape by crossing whatever lake or river he happens to approach. While swimming he takes all possible care to keep in the middle of the stream, least, by touching the bough of a tree or the herbage on the banks, he may give scent to the hounds. He is also ever found to swim against the stream—whence the huntsmen have made it into a kind of proverb, that "He that would his chase find, must up with the river and down with the wind." On this occasion, too, he will often cover himself under water, so as to show nothing but the tip of his nose. Every resource and every art being at length exhausted, the poor creature tries the last remains of its strength by boldly opposing those enemies he cannot escape; he therefore faces the dogs and men, threatens with his horns, guards himself on every side, and for some time stands at bay. In this manner, quite desperate, he furiously aims at the first dog or man that approaches; and it often happens that he does not die unrevenge. At that time the more prudent, both of the dogs and men, seem wishful to avoid him; but the whole pack quickly coming up, he is soon surrounded and brought down, and the huntsman winds a "treble mort," as it is called, with his horn.

Such is the manner of pursuing this animal in England; but every country has a peculiar method of its

own, adapted either to the nature of the climate or the face of the soil. The ancient manner was very different from that practised at present; they used their dogs only to find out the game, but not to rouse it. Hence they were not curious as to the music of their hounds or the composition of their pack; the dog that opened before he had discovered his game was held in no estimation. It was their usual manner silently to find out the animal's retreat, surrounding it with nets and engines; then drove him up with boisterous cries, and thus forced him into the toils which they had previously prepared. In succeeding time the fashion seemed to alter; more particularly in Sicily, where the manner of hunting was as follows:—The nobles and gentry, being informed which way a herd of deer passed, gave notice to each other, and appointed a day of hunting. For this purpose everyone was to bring a cross-bow or a long-bow, and a bundle of staves shod with iron, the heads bored, with a cord passing through them all. Thus provided, they came to where the herd continued grazing, and, spreading themselves about in a large circle, surrounded the deer on every side; then, each taking his stand, unbound his faggot, set up his stake, and tied the end of the cord to that of his next neighbour, at the distance of about ten feet one from the other. Between each of these stakes was hung a bunch of crimson feathers, so disposed, that with the least breath of wind they would whirl round, and preserve a sort of fluttering motion. This done, the persons who set up the staves withdrew and hid themselves in the adjacent coverts; then the chief huntsman, entering with his hounds within the lines, roused the game with a full cry. The deer, frightened and flying on all sides, on approaching the lines were scared away by the fluttering of the feathers, and wandered about within this artificial paling, still awed by the shining and fluttering plumage that encircled their retreat—the huntsman, however, still pursuing, and, calling every person by name as he passed by their stand, commanded him to shoot the first, third, or sixth, as he pleased; and if any of them missed, or singled out another than that assigned him, it was considered a shameful mischance. In this manner, however, the whole herd was at last destroyed, and the day concluded with mirth and feasting.

The stags of China are of a particular kind, for they are no taller than a common house-dog; and hunting them is one of the principal diversions of the great. Their flesh while young is exceedingly good; but when they arrive at maturity it begins to grow hard and tough: however, the tongue, the muzzle, and the ears are in particular esteem among that luxurious people. Their manner of taking them is singular enough. They carry with them the heads of some of the females stuffed, and learn exactly to imitate their cry; upon this the male does not fail to appear, and, looking on all sides, perceives the head—which is all that the hunter (who is himself concealed) discovers. Upon their nearer approach the whole company rise, surround, and often take him alive.

There are very few varieties of the red deer in this country, and they are mostly found of the same size and colour. But it is otherwise in different parts of the world, where they are seen to differ in form, in size, in horns, and in colour.

The stag of Corsica is a very small animal, being not above half the size of those common among us. His body is short and thick, his legs short, and his hair of a dark brown.

There is in the forests of Germany a kind of stag, named by the ancients the "Tragelaphus," and which the natives call the "bran deer," or the "brown deer." This is of a darker colour than the common stag, of a lighter shade upon the belly, long hair upon the neck and throat, by which it appears bearded like the goat.

There is also a very beautiful stag, which by some is

said to be a native of Sardinia; but others (among whom is Mr. Buffon) are of opinion that it comes from Africa or the East Indies. He calls it the "axis," after Pliny; and considers it as making the shade between the stag and the fallow deer. The horns of the axis are round, like those of the stag; but the form of the body entirely resembles that of the buck, and the size also is exactly the same. The hair is of four colours; namely, fallow, white, black, and grey. The white is predominant under the belly on the inside of the thighs and the legs. Along the back there are two rows of spots in a right line; but those on other parts of the body are very irregular. A white line runs along each side of this animal while the head and neck are grey. The tail is black above and white beneath; and the hair upon it is six inches long.

Although there are but few individuals of the deer kind, yet the race seems diffused over all parts of the earth. The new continent of America, in which neither the sheep, the goat, nor the gazelle have been originally bred, nevertheless produces stags and other animals of the deer kind in sufficient plenty. The Mexicans have a breed of white stags in their parks, which they call "stags royal." The stags of Canada differ from ours in nothing except the size of the horns, which in them is greater, and the direction of the antlers, which rather turn back than project forward as in those of Europe. The same difference of size that obtains among our stags is also to be seen in that country; and, as we are informed by Ruysch, the Americans have brought them into the same state of domestic tameness that we have our sheep, goats, or black cattle. They send them forth in the daytime to feed in the forests; and at night they return home with the herdsman who guards them. The inhabitants have no other milk but what the hind produces, and use no other cheese but what is made from thence. In this manner we find that an animal which seems made only for man's amusement may be easily brought to supply his necessities. Nature has many stores of happiness and plenty in reserve, which only want the call of industry to be produced, and now remain as candidates for human approbation.

**THE FALLOW DEER.**—No two animals can be more nearly allied than the stag and the fallow deer. Alike in form, alike in disposition, in the superb furniture of their heads, in their swiftness and timidity; and yet no two animals keep more distinct, or avoid each other with more fixed animosity. They are never seen to herd in the same place; they never engender together, or form a mixed breed; and even in those countries where the stag is common the buck seems to be entirely a stranger; in short, they both form distinct families, which though so seemingly near are still remote; and although with the same habitudes, yet retain an unalterable aversion. The fallow deer, as they are much smaller, so they seem of a nature less robust and less savage than those of the stag kind. They are found but rarely wild in the forests; they are in general bred up in parks, and kept for the purposes of hunting or of luxury, their flesh being preferred to that of any other animal. It need scarce be mentioned that the horns of the buck make its principal distinction, being broad and palmated; whereas those of the stag are in every part round. In the one, they are flattened and spread like the palm of the hand; in the other they grow like a tree, every branch being of the shape of the stem that bears it. The fallow deer also has the tail longer and the hair lighter than the stag; in other respects they pretty near resemble one another.

The head of the buck, as of all other animals of this kind, is shed every year, and takes the usual time for repairing. The only differences between it and the stag is, that this change happens later in the buck; and its rutting time consequently falls most into the winter. It is not found so furious at this season as the former; nor does it so much exhaust itself by the violence of

its ardour. It does not quit its natural pastures in quest of the female, nor does it attack other animals with indiscriminate ferocity; however, the males combat for the female among each other; and it is not without many contests that one buck is seen to become master of the whole herd. It often happens, also, that a herd of fallow deer is seen to divide into two parties, and engage each other with great ardour and obstinacy. They both seem desirous of gaining some favourite spot of the park for pasture, and of driving the vanquished party into the coarser and more disagreeable parts. Each of these factions has its particular chief; namely, the two oldest and strongest of the herd. These lead on to the engagement; and the rest follow under their direction. These combats are singular enough, from the disposition and conduct which seems to regulate their mutual efforts. They attack with order, and support the assault with courage; they come to each other's assistance; they retire, they rally, and never give up the victory upon a single defeat. The combat is renewed for several days together; until at length the most feeble side is obliged to give way, and is content to escape to the most disagreeable part of the park, where only they can find safety and protection.

The fallow-deer is easily tamed, and feeds upon many things which the stag refuses. By this means it preserves its venison better; and even after rutting it does not appear entirely exhausted. It continues almost in the same state through the whole year, although there are particular seasons when its flesh is chiefly in esteem. This animal also browses closer than the stag; for which reason it is more prejudicial among young trees, which it often strips too close for recovery. The young deer eat much faster and more greedily than the old; they seek the female at their second year, and, like the stag, are fond of variety. The deer goes with young above eight months, like the hind, and commonly brings forth one at a time; but they differ in this, that the buck comes to perfection at three and lives till sixteen; whereas the stag does not come to perfection till seven, and lives till forty.

As this animal is a beast of chase, like the stag, so the hunters have invented a number of names relative to him. The buck is the first year called a fawn; the second, a pricket; the third, a sorel; the fourth, a sore; the fifth, a buck of the first head; and the sixth, a great bucky. The female is called a doe; the first year, a fawn; and the second, a tegg. The manner of hunting the buck is pretty much the same as stag-hunting, except that less skill is required in the latter. The buck is more easily roused; it is sufficient to judge by the view, and mark what grove or covert it enters—as it is not known to wander far from thence, nor, like the stag, to change its layer or place of repose. When severely hunted, it takes to some strong-hold or covert with which it is acquainted in the more gloomy parts of the wood or the steep of the mountain—not like the stag, flying before the hounds, nor crossing nor doubling, nor using any of the subtleties which the stag is accustomed to. It will take the water when sorely pressed, but seldom a great river; nor can it swim so long nor so swiftly as the former. In general, the strength, the cunning, and the courage of this animal are inferior to those of the stag; consequently it affords neither so long, so various, nor so obstinate a chase; besides, being lighter and not tracing so deeply, it leaves a less powerful and lasting scent, and the dogs in the pursuit are frequently at fault.

As the buck is a more delicate animal than the stag, so also it is subject to greater varieties. We have in England two varieties of the fallow deer, which are said to be of foreign origin—the beautiful spotted kind, which is supposed to have been brought from Bengal; and the very deep brown sort, that are now so common in several parts of this kingdom. These were introduced by King

James the First from Norway; for, having observed their hardiness, and that they could endure the winter even in that severe climate without fodder, he brought over some of them into Scotland, and disposed of them among his chases. Since that time they have multiplied in many parts of the British empire; and England is now become more famous for its venison than any other country in the world. Whatever pains the French have taken to rival us in this particular, the flesh of their fallow deer, of which they have but few, has neither the fatness nor the flavour of that fed upon English pasture.

However, there is scarce a country in Europe, except far to the northward, in which this animal is a stranger. The Spanish fallow deer are as large as stags, but of a darker colour and a more slender neck: their tails are longer than those of ours—they are black above and white below. The Virginian deer are larger and stronger than ours, with great necks, and their colour inclinable to grey. Other kinds have the hoofs of their hind-legs marked outwardly with a white spot, and their ears and tails much longer than the common. One of these has been seen full of white spots, with a black list down the middle of his back. In Guiana, a country of South America, according to Labat, there are deer without horns, which are much less than those of Europe, but resembling them in every other particular. They are very lively, light of course, and excessively fearful; their hair is of a redish fallow, their heads are small and lean, their ears little, their necks long and arched, the tail short, and the sight piercing. When pursued, they fly into places where no other animal can follow them. The Negroes who pursue them stand to watch for them in narrow paths which lead to the brook or the meadow where they feed, waiting in the utmost silence, for the slightest sound will drive them away; the Negro, when he perceives the animal within reach, shoots, and is happy if he can bring down his game. Their flesh, though seldom fat, is considered as a great delicacy, and the hunter is well rewarded for his trouble.

**THE ROEBUCK.**—The roebuck is the smallest of the deer kind known in our climate, and is now almost extinct among us, except in some parts of the Highlands of Scotland. It is generally about three feet long, and about two feet high. The horns are from eight to nine inches long, upright, round, and divided into only three branches. The body is covered with very long hair, well adapted to the rigour of its mountainous abode. The lower part of each hair is ash colour; near the ends is a narrow bar of black, and the points are yellow. The hairs on the face are black, tipped with ash colour. The ears are long, their insides of a pale yellow, and covered with long hair. The spaces bordering on the eyes and mouth are black. The chest, belly, and legs, and the inside of the thighs, are of a yellowish white; the rump is of a pure white, and the tail very short. The make of this little animal is very elegant; and its swiftness equals its beauty. It differs from the fallow-deer in having round horns, and not flatted like theirs. It differs from the stag in its smaller size, and the proportionable paucity of its antlers: and it differs from all of the goat kind, as it annually sheds its horns, and obtains new ones, which none of that kind are ever seen to do.

As the stag frequents the thickest forests and the sides of the highest mountains, the roebuck, with humbler ambition, courts the shady thicket and the rising slope. Although less in size and far inferior in strength to the stag, it is yet more beautiful, more active, and even more courageous. Its hair is always smooth, clean, and glossy; and it frequents only the driest places and inhales the purest air. Though but a very little animal, as we have already observed, yet when its young is attacked it faces even the stag himself, and often comes off victorious. All its motions are elegant and easy; it bounds without effort, and continues the course with but little fatigue.

It is also possessed of more cunning in avoiding the hunter, is more difficult to pursue, and although its scent is much stronger than that of the stag, it is more frequently found to make a good retreat. It is not with the roebuck as with the stag, who never offers to use art until his strength is beginning to decline; this more cunning animal, when it finds that its first efforts to escape are without success, returns upon its former track, again goes forward and again returns, until by its various windings it has entirely confounded the scent, and joined the last emanations to those of its former course. It then by a bound goes to one side, lies flat upon its belly, and permits the pack to pass by very near without offering to stir.

But the roebuck differs not only from the stag in superior cunning, but also in its natural appetites, its inclinations, and its whole habits of living. Instead of herding together, these animals live in separate families; the sire, the dam, and the young ones associate together, and never admit a stranger into their little community. All others of the deer kind are inconstant in their affection; but the roebuck never leaves its mate; and, as they have been generally bred up together from their first fawning, they conceive so strong an attachment the male for the female that they never after separate. Their rutting season continues but fifteen days—from the latter end of October to about the middle of November. They are not at that time, like the stag, overloaded with fat; they have not that strong odour which is perceived in all others of the deer kind; they have none of those furious excesses—nothing, in short, that alters their state: they only drive away their fawns upon these occasions—the buck forcing them to retire in order to make room for a succeeding progeny; however, when the copulating season is over the fawns return to their dams, and remain with them some time longer; after which they quit them entirely, in order to begin an independent family of their own. The female goes with young but five months and a half, which alone serves to distinguish this animal from all others of the deer kind that continue pregnant more than eight. In this respect she approaches more nearly to the goat kind; from which, however, this race is separated by the male's annually casting its horns.

When the female is ready to bring forth she seeks a retreat in the thickest parts of the woods, being not less apprehensive of the buck, from whom she then separates, than of the wolf, the wild cat, and almost every ravenous animal of the forest; she generally produces two at a time, and three but very rarely. In about ten or twelve days these are able to follow their dam, except in cases of warm pursuit, when their strength is not equal to the fatigue. Upon such occasions the tenderness of the dam is very extraordinary; leaving them in the deepest thickets, she offers herself to the danger, flies before the hounds, and does all in her power to lead them from the retreat where she has lodged her little ones. Such animals as are nearly upon her own level she boldly encounters; attacks the stag, the wild cat, and even the wolf; and while she has life continues her efforts to protect her young. Yet all her endeavours are often vain; about the month of May, which is her fawning time, there is a greater destruction among those animals than at any other season of the year. Numbers of fawns are taken alive by the peasants; numbers are found out and worried by the dogs; and still more by the wolf, which has always been their most inveterate enemy. By these continual depredations upon this beautiful creature the roebuck is every day becoming scarcer; and the whole race in many countries is wholly worn out. They were once common in England; the hunters, who characterised only such beasts as they knew, have given names to the different kinds and ages as to the stag; thus they call it the first year the hind, the second a gyrlie, and the third a hemuse; but these names

at present are utterly useless, since the animal no longer exists among us. Even in France, where it was once extremely common, it is now confined to a few provinces; and it is probable that in an age or two the whole breed will be utterly extirpated. Mr. Buffon, indeed, observed that in those districts where it is mostly found it seems to maintain its usual plenty, and that the balance between its destruction and increase is held pretty even; however, the number in general is known to decrease; for wherever cultivation takes place the beasts of Nature are known to retire. Many animals that once flourished in the world may now be extinct; and the descriptions of Aristotle and Pliny, though taken from life, may be considered as fabulous, as their archetypes are no longer existing.

The fawns continue to follow the deer eight or nine months in all; and upon separating their horns begin to appear—simple and without antlers the first year, as in those of the stag kind. These they shed at the latter end of autumn, and renew during the winter—differing in this from the stag, who sheds them in spring and renews them in summer. When the roebuck's head is completely furnished it rubs its horns against trees in the manner of the stag, and thus strips them of the rough skin and the blood-vessels, which no longer contribute to their nourishment and growth. When these fall and new ones begin to appear, the roebuck does not retire like the stag to the covert of the wood, but continues its usual haunts, only keeping down its head to avoid striking its horns against the branches of trees, the pain of which it seems to feel with exquisite sensibility. The stag, who sheds his horns in summer, is obliged to seek a retreat from the flies, which at that time greatly incommode him; but the roebuck, who sheds them in winter, is under no such necessity, and consequently does not separate from his little family, but keeps with the female all the year round.

As the growth of the roebuck and its arrival at maturity are much speedier than that of the stag, so its life is proportionably shorter. It seldom is found to extend above twelve or fifteen years; and if kept tame it does not live above six or seven. It is an animal of a very delicate constitution, requiring variety of food, air, and exercise. It must be paired with a female, and kept in a park of at least a hundred acres. They may easily be subdued, but never thoroughly tamed. No arts can teach them to be on familiar terms with the feeder, much less attached to him. They still preserve a part of their natural wildness, and are subject to terrors without a cause. They sometimes, in attempting to escape, strike themselves with such force against the walls of their inclosure, that they break their limbs and become quite disabled. Whatever care is taken to tame them they are never entirely to be relied on, as they have capricious fits of fierceness, and sometimes strike at those they dislike with a degree of force that is very dangerous.

The cry of the roebuck is neither so loud nor so frequent as that of the stag. The young ones have a particular manner of calling to the dam, which the hunters easily imitate, and often thus allure the female to her destruction. On some occasions, also, they become in a manner intoxicated with their food, which during the spring is said to ferment in their stomachs, and they are then very easily taken. In summer they keep close under covert of the forest, and seldom venture out, except in violent heats, to drink at some river or fountain. In general, however, they are contented to slake their thirst with the dew that falls on the grass and on the leaves of trees, and seldom risk their safety to satisfy their appetite. They delight chiefly in hilly grounds, preferring the tender branches and buds of trees to corn or other vegetables; and it is universally allowed that the flesh of those between one and two years old is the greatest delicacy known. Perhaps its scarceness also enhances its flavour.

In America this animal is much more common than in Europe. With us there are but two known varieties—the red, which is the largest sort; and the brown, with a spot behind, which is less. But in the new continent the breed is extremely numerous, and the varieties in equal proportion. In Louisiana, where they are extremely common, they are much larger than in Europe, and the inhabitants live in a great measure upon its flesh, which tastes like mutton when well fattened. They are also found in Brazil, where they have the name of "cagacu apara," only differing from ours in some slight deviations in the horns. This animal is also said to be common in China, although such as have described it seem to confound it with the musk goat, which is quite of a different nature.

**THE ELK.**—We have hitherto been describing minute animals in comparison of the elk—the size of which, from concurrent testimony, appears to equal that of the elephant itself. It is an animal rather of the buck than the stag kind, as its horns are flatted towards the top; but it is far beyond both in stature, some of them being known to be above ten feet high. It is a native both of the old and new continent, being known in Europe under the name of the "elk," and in America by that of the "moose-deer." It is sometimes taken in the German and Russian forests, although seldom appearing; but it is extremely common in North America, where the natives pursue and track it in the snow. The accounts of this animal are extremely various—some describing it as being no higher than a horse, and others about twelve feet high.

As the stature of this creature makes its chief peculiarity, so it were to be wished that we could come to some precision upon that head. If we were to judge of its size by the horns, which are sometimes fortuitously dug up in many parts of Ireland, we should not be much amiss in ascribing them to an animal ten feet high. One of these I have seen, which was ten feet nine inches from one tip to the other. From such dimensions it is easy to perceive that it required an animal far beyond the size of a horse to support them. To bear a head with such extensive and heavy antlers required no small degree of strength; and without all doubt the bulk of the body must have been proportionable to the size of the horns. I remember some years ago to have seen a small moose-deer, which was brought from America by a gentleman of Ireland; it was about the size of a horse, and the horns were very little larger than those of a common stag: this, therefore, serves to prove that the horns bear an exact proportion to the animal's size; the small elk has but small horns; whereas those enormous ones which we have described above must have belonged to a proportionable creature. In all the more noble animals Nature observes a perfect symmetry; and it is not to be supposed she fails in this single instance. We have no reason, therefore, to doubt the accounts of Jocelyn and Dudley, who affirm that they have been found fourteen spans, which, at nine inches to a span, makes the animal almost eleven feet high. Others have extended their accounts to twelve and fourteen feet, which makes this creature one of the most formidable of the forest.

There is but very little difference between the European elk and the American moose-deer, as they are but varieties of the same animal. It may be rather larger in America than with us; as in the forests of that unpeopled country it receives less disturbance than in our own. In all places, however, it is timorous and gentle—content with its pasture, and never willing to disturb any other animal when supplied itself. The European elk grows to above seven or eight feet high. In the year 1742 there was a female of this animal shown at Paris, which was caught in a forest of Red Russia, belonging to the Cham of Tartary; it was then but young, and its height was even at that time six feet seven inches; but the describer

observes that it has since become much taller and thicker, so that we may suppose this female at least seven feet high. There have been no late opportunities of seeing the male; but, by the rule of proportion, we may estimate his size at eight or nine feet at the least, which is about twice as high as an ordinary horse. The height, however, of this female which was measured was but six feet seven inches Paris measure, or almost seven English feet high. It was ten feet from the tip of the nose to the insertion of the tail, and eight feet round the body. The hair was very long and coarse, like that of a wild boar. The ears resembled those of a mule, and were a foot and a half long. The upper jaw was longer by six inches than the lower; and, like other ruminating animals, it had no teeth (cutting teeth, I suppose the describer means). It had a large beard under the throat, like a goat; and in the middle of the forehead, between the horns, there was a bone as large as an egg. The nostrils were four inches long on each side of the mouth. It made use of its fore-feet as a defence against its enemies. Those who showed it asserted that it ran with astonishing swiftness, and that it swam with equal expedition, and was very fond of the water. They gave it thirty pounds of bread every day, besides hay, and it drank eight buckets of water. It was tame and familiar, and submissive enough to its keeper.

This description differs in many circumstances from that which we have of the moose or American elk, which the French call the original. Of these there are two kinds—the common light grey moose, which is not very large; and the black moose, which grows to an enormous height. Mr. Dudley observes that a doe or hind of the black moose kind of the fourth year wanted but an inch of being seven feet high. All, however, of both kinds have flat palmed horns, not unlike the fallow-deer, only that the palm is much larger, having a short trunk at the head, and then immediately spreading above a foot broad, with a kind of small antlers like teeth on one of the edges. In this particular all of the elk kind agree, as well the European elk as the grey and the black moose-deer.

The grey moose deer is about the size of a horse, and although it has large buttocks its tail is not more than an inch long. As in all of this kind the upper lip is much longer than the under, it is said that they continue to go back as they feed. Their nostrils are so large that a man may thrust his hand in a considerable way; and their horns are as long as those of a stag, but, as was observed, much broader.

The black moose is the enormous animal mentioned above, from eight to twelve feet high. Jocelyn, who is the first English writer that mentions it, says that it is a goodly creature twelve feet high, with exceeding fair horns, which have broad palmas, two fathoms from the top of one horn to another. He assures us that it is a creature, or rather a monster, of superfluity, and many times bigger than an English ox. This account is confirmed by Dudley; but he does not give so great an expansion to the horns, measuring them only thirty-one inches between one tip and the other: however, that such an extraordinary animal as Jocelyn describes has actually existed we can make no manner of doubt, since there are horns common enough to be seen among us twelve feet from one tip to the other.

These animals delight in cold countries, feeding upon grass in summer and the bark of trees in winter. When the whole country is deeply covered with snow the moose-deer herd together under the tall pine-trees, strip off the bark, and remain in that part of the forest while it yields them subsistence. It is at that time that the natives prepare to hunt them, particularly when the sun begins to melt the snow by day, which is frozen again at night; for then the icy crust which covers the surface of the snow is too weak to support so great a bulk, and only retards the animal's motion. When the Indians,

therefore, perceive a herd of these at a distance they immediately prepare for pursuit—which is not, as with us, the sport of an hour, but is attended with toil, difficulty, and danger. The timorous animal no sooner observes its enemies approach than it immediately endeavours to escape, but sinks at every step it takes. Still, however, it pursues its way through a thousand obstacles; the snow, which is usually four feet deep, yields to its weight and embarrasses its speed; the sharp ice wounds its feet; and its lofty horns are entangled in the branches of the forest as it passes along. The trees, however, are broken down with ease; and wherever the moose-deer runs it is perceived by the snapping off the branches of the trees, as thick as a man's thigh, with its horns. The chase lasts in this manner for the whole day, and sometimes it has been known to continue for two or three days together—for the pursuers are often not less excited by famine than the pursued by fear. Their perseverance, however, generally succeeds; and the Indian who first comes near enough darts his lance with unerring aim, which sticks in the poor animal, and at first increases its efforts to escape. In this manner the moose trots heavily on (for that is its usual pace) until its pursuers come up and repeat the blow: upon this it again summons up sufficient vigour to get ahead; but at last, quite tired and spent with loss of blood, it sinks (as the describer expresses it) like a ruined building, making the earth shake beneath its fall.

This animal when killed is a valuable acquisition to the hunters. The flesh is exceedingly well tasted, and is said to be very nourishing. The hide is strong, and so thick that it has been often known to turn a musket-ball; however, it is soft and pliable, and when tanned, the leather is extremely light, yet very lasting. The fur is a light grey in some and blackish in others; and through a microscope appears spongy like a bulrush, and is smaller at the roots and points than in the middle; for this reason it lies very flat and smooth, and, though beaten or abused never so much, it always returns to its former state. The horns are not less useful, being applied to all the purposes for which hartshorn is beneficial: these are different in different animals; in some they resemble those of the European elk, which spread into a broad palm, with small antlers on one of the edges; in others they have a branched brow antler between the bur and the palm, which the German elk has not; and in this they entirely agree with those whose horns are so frequently dug up in Ireland. This animal is said to be troubled with the epilepsy, as it is often found to fall down when pursued, and thus becomes an easier prey; for this reason—an imaginary virtue has been ascribed to the hinder hoof, which some have supposed to be a specific against all epileptic disorders. This, however, may be considered as a vulgar error; as well as that of its curing itself of this disorder by applying the hinder hoof behind the ear. After all, this animal is but very indifferently and confusedly described by travellers—each mixing his account with something false or trivial; often mistaking some other animal for the elk, and confounding its history. Thus some have mistaken it for the rein-deer, which in everything but size it greatly resembles; some have supposed it to be the same with the tapurette, from which it entirely differs; some have described it as the common red American stag, which scarcely differs from our own; and, lastly, some have confounded it with the bubalus, which is more properly a gazelle of Africa.

**THE REIN-DEER.**—Of all animals of the deer kind the rein-deer is the most extraordinary and the most useful. It is a native of the icy regions of the north; and though many attempts have been made to acustom it to a more southern climate, it shortly feels the influence of the change, and in a few months declines and dies. Nature seems to have fitted it entirely to answer the necessities

of that hardy race of mankind that live near the pole. As these would find it impossible to subsist among their barren snowy mountains without its aid, so this animal can live only there, where its assistance is most absolutely necessary. From it alone the natives of Lapland and Greenland supply most of their wants; it answers the purposes of a horse to convey them and their scanty furniture from one mountain to another; it answers the purposes of a cow in giving milk; and it answers the purposes of the sheep in furnishing them with a warm though a homely kind of clothing. From this quadruped alone, therefore, they receive as many advantages as we derive from three of our most useful creatures; so that Providence does not leave these poor outcasts entirely destitute, but gives them a faithful domestic, more patient and serviceable than any other in Nature.

The rein-deer resembles the American elk in the fashion of its horns. It is not easy in words to describe these minute differences; nor will the reader, perhaps, have a distinct idea of the similitude when told that both have brow-antlers, very large, and hanging over their eyes, palmated towards the top, and bending forward like a bow. But here the similitude between these two animals ends; for, as the elk is much larger than the stag, so the rein-deer is much smaller. It is lower and stronger built than the stag; its legs are shorter and thicker, and its hoofs much broader than in that animal; its hair is much thicker and warmer, its horns much larger in proportion, and branching forward over its eyes; its ears are much larger; its pace is rather a trot than bounding, and this it can continue for a whole day; its hoofs are cloven and moveable, so that it spreads them abroad as it goes to prevent its sinking in the snow. When it proceeds on a journey it lays its great horns on its back, while there are two branches which always hang over its forehead and almost cover its face. One thing seems peculiar to this animal and the elk—which is, that as they move along their hoofs are heard to crack with a pretty loud noise. This arises from their manner of treading; for as they rest upon their cloven hoof it spreads on the ground, and the two divisions separate from each other, but when they lift it the divisions close again, and strike against each other with a crack. The female, also, of the rein-deer has horns as well as the male, by which the species is distinguished from all other animals of the deer kind whatsoever.

When the rein-deer first shed their coat of hair they are brown; but in proportion as summer approaches their hair begins to grow whitish, until at last they are nearly grey. They are, however, always black about the eyes. The neck has long hair, hanging down, and coarser than upon any other part of the body; the feet at the insertion of the hoof are surrounded with a ring of white; the hair in general stands so thick over the whole body, that if one should attempt to separate it the skin will nowhere appear uncovered: whenever it falls, also, it is not seen to drop from the root, as in other quadrupeds, but seems broken short near the bottom; so that the lower part of the hair is seen growing while the upper part falls away. The horns of the female are made like those of the male, except that they are smaller and less branching. As in the rest of the deer kind they sprout from the points; and in the beginning they are furnished with a hairy crust, which supports the blood-vessels, of most exquisite sensibility. The rein-deer shed their horns after rutting time, at the latter end of November; and they are not completely furnished again till towards autumn. The female always retains hers till she brings forth, and then sheds them about the beginning of November. If she be barren, however (which is not unfrequently the case), she does not shed them while winter. The castration of the rein-deer does not prevent the shedding of their horns; those which are the strongest cast them early in winter—those which are most weakly not so soon. Thus,

from all these circumstances we see how greatly this animal differs from the common stag. The female of the rein-deer has horns, which the hind is never seen to have; the rein-deer when castrated renews its horns, which we are assured the stag never does. It differs not less in its habits and manner of living, being tame, submissive, and patient; while the stag is wild, capricious, and unmanageable.

The rein-deer, as was said, is naturally an inhabitant of the countries bordering on the arctic circle. It is not unknown to the natives of Siberia. The North Americans also hunt it under the name of the "caribou." But in Lapland this animal is appropriated to the most advantage; and some herdsmen of that country are known to possess above a thousand in a single herd.

Lapland is divided into two districts—the mountainous and the woody. The mountainous part of the country is at best barren and bleak, excessively cold, and uninhabitable during the winter; still, however, it is the most desirable part of this frightful region, and is most thickly peopled during the summer. The natives generally reside on the declivity of the mountains, three or four cottages together, and lead a cheerful and social life. On the approach of winter they are obliged to migrate into the plains below, each bringing down his whole herd, which often amounts to more than a thousand, and leading them where the pasture is in greatest plenty. The woody part of the country is much more desolate and hideous: the whole face of Nature there presents a frightful scene of trees without fruit and plains without verdure. As far as the eye can reach nothing is to be seen, even in the midst of summer, but barren fields, covered only with a moss almost as white as snow; no grass, no flowery landscapes—only here and there a pine-tree, which may have escaped the frequent conflagrations by which the natives burn down their forests. But what is more extraordinary, as the whole surface of the country is clothed in white, so on the contrary the forests seem to the last degree dark and gloomy. While one kind of moss makes the fields look as if they were covered with snow, another kind blackens over all their trees, and even hides their verdure. This moss, however, which darkens the country serves for its only support, as upon it alone the rein-deer can subsist. The inhabitants (who, during the summer, live among the mountains) drive down their herds in winter, and people the plains and woods below. Such of the Laplanders as inhabit the woods and plains throughout the year live remote from each other, and, having been used to solitude, are melancholy, ignorant, and helpless. They are much poorer, also, than the mountaineers; for while one of those is found to possess a thousand rein-deer at a time, none of these are ever known to rear the tenth part of that number. The rein-deer makes the riches of this people; and the cold mountainous parts of the country agree best with its constitution. It is for this reason, therefore, that the mountains of Lapland are preferred to the woods, and that many claim an exclusive right to the tops of hills covered in almost snow. As soon as the summer begins to appear the Laplander, who had fed his rein-deer upon the lower grounds during the winter, then drives them up to the mountains, and leaves the woody country and the low pasture, which at that season are truly deplorable. The gnats, bred by the sun's heat in the marshy bottoms and the weedy lakes with which the country abounds more than any other part of the world, are all upon the wing and fill the whole air, like clouds of dust in a dry windy day. The inhabitants at that time are obliged to daub their faces with pitch, mixed with milk, to shield their skins from their depredations. All places are then so greatly infested that the poor natives can scarce open their mouths without fear of suffocation; the insects enter, from their numbers and minuteness, into the nostrils and the eyes, and do not leave the sufferer a

moment at his ease. But they are chiefly enemies to the rein-deer: the horns of that animal being then in their tender state, and possessed of extreme sensibility, a furnished cloud of insects instantly settle upon them, and drive the poor animal almost to distraction. In this extremity there are but two remedies, to which the quadruped as well as its master are obliged to have recourse. The one is, for both to take shelter near their cottage, where a large fire of tree-moss is prepared, which, filling the whole place with smoke, keeps off the gnat, and thus by one inconvenience expels a greater; the other is, to ascend to the highest summit of the mountains, where the air is too thin and the weather too cold for the gnats to come. There the rein-deer are seen to continue the whole day, although without food, rather than venture down to the lower parts, where they can have no defence against their unceasing persecutors. Besides the gnat, there is also a gadfly, that during the summer season is no less formidable to them. This insect is bred under their skins, where the egg has been deposited the preceding summer: and it is no sooner produced as a fly than it again endeavours to deposit its eggs in some place similar to that from whence it came. Whenever, therefore, it appears flying over a herd of rein-deer, it puts the whole body, how numerous soever, into motion; they know their enemy, and do all they can, by tossing their horns and running among each other, to terrify or avoid it. All their endeavours, however, are too generally without effect; the gadfly is seen to deposit its eggs, which, burrowing under the skin, wound it in several places, and often bring on an incurable disorder. In the morning, therefore, as soon as the Lapland herdsman drives his deer to pasture, his greatest care is to keep them from scaling the summits of the mountains where there is no food, but where they go merely to be at ease from the gnats and gadflies that are ever annoying them. At this time there is a strong contest between the dogs and the deer—the one endeavouring to climb up against the side of the hill, and to gain those summits that are covered in eternal snow; the other forcing them down by barking and threatening, and, in a manner, compelling them to go to the places where their food is in the greatest plenty. There the men and dogs confine them—guarding them with the utmost precaution the whole day, and driving them home at the proper seasons for milking.

The female brings forth in the middle of May, and gives milk till about the middle of October. Every morning and evening during the summer the herdsman returns to the cottage with his deer to be milked, where the women previously have kindled up a smoky fire, which effectually drives off the gnats, and keeps the rein-deer quiet while milking. The female furnishes about a pint, which, though thinner than that of the cow, is, nevertheless, sweeter and more nourishing. This done, the herdsman drives them back to pasture—as he neither folds nor houses them, neither provides for their subsistence during the winter, nor improves their pasture by cultivation.

On the return of winter, when the gnats and flies are no longer to be feared, the Laplander descends into the lower grounds; and, as there are but few to dispute the possession of that desolate country, he has an extensive range to feed them in. Their chief and almost their only food at that time is the white moss already mentioned; which, from its being fed upon by this animal, obtains the name of the "*lichen rangiferinus*." This is of two kinds—the woody lichen, which covers almost all the desert parts of the country like snow; the other is black, and covers the branches of the trees in very great quantities. However unpleasing these may be to the spectator, the native esteems them as one of his choicest benefits and the most indulgent gift of Nature. While his fields are clothed with moss he envies neither the fertility nor the verdure of the more southern landscape,

dressed up warmly in his deer-skin clothes, with shoes and gloves of the same materials, he drives his herds along the desert, fearless and at ease, ignorant of any higher luxury than what their milk and smoke-dried flesh affords him. Hardened to the climate, he sleeps in the midst of ice; or, awaking, dozes away his time with tobacco; while his faithful dogs supply his place and keep the herd from wandering. The deer in the meantime, with instincts adapted to the soil, pursue their food, though covered in the deepest snow. They turn it up with their noses like swine; and, even though its surface be frozen and stiff, yet the hide is so hardened in that part that they easily overcome the difficulty. It sometimes, however, happens, though but rarely, that the winter commences with rain, and a frost ensuing, covers the whole country with a glazed crust of ice. Then, indeed, both the rein-deer and the Laplander are undone; they have no provisions laid up in case of accident, and the only resource is to cut down the large pine-trees that are covered with moss, which furnish but a scanty supply; so that the greatest part of the herd is then seen to perish without a possibility of assistance. It sometimes also happens that even this supply is wanting; for the Laplander often burns down his woods in order to improve and fertilise the soil which produces the moss upon which he feeds his cattle.

In this manner the pastoral life is still continued near the pole; neither the coldness of the winter nor the length of the nights—neither the wildness of the forest nor the vagrant disposition of the herd, interrupt the even tenor of the Laplander's life. By night and day he is seen attending his favourite cattle, and remains unaffected in a season which would be speedy death to those bred up in a milder climate. He gives himself no uneasiness to house his herds, or to provide a winter subsistence for them; he is at the trouble neither of manuring his grounds nor bringing in his harvests; he is not the hireling of another's luxury;—all his labours are to obviate the necessities of his own situation; and these he undergoes with cheerfulness, as he is sure to enjoy the fruits of his own industry. If, therefore, we compare the Laplander with the peasant of more southern climates, we shall have little reason to pity his situation; the climate in which he lives is rather terrible to us than to him; and as for the rest, he is blessed with liberty, plenty, and ease. The rein-deer alone supplies him with all the wants of life and some of the conveniences—serving to show how many advantages Nature is capable of supplying when Necessity gives the call. Thus the poor, little, helpless native, who was originally, perhaps, driven by fear or famine into those inhospitable climates, would seem at first view to be the most wretched of mankind; but it is far otherwise; he looks round among the few wild animals that his barren country can maintain, and singles out one from among them, and that of a kind which the rest of mankind have not thought worth taking from a state of nature; this he cultivates, propagates, and multiplies, and from this alone derives every comfort that can soften the severity of his situation.

The rein-deer of this country are of two kinds—the wild and the tame. The wild are larger and stronger, but more mischievous than the others. Their breed, however, is preferred to that of the tame; and the female of the latter is often sent into the woods, from whence she returns home impregnated by one of the wild kind. These are fitter for drawing the sledge, to which the Laplander accustoms them betimes, and yokes them to it by a strap, which goes round the neck, and comes down between their legs. The sledge is exceedingly light, and shod at the bottom with the skin of a young deer, the hair turned to slide on the frozen snow. The person who sits on this guides the animal with a cord fastened round the horns, encouraging it to proceed with his voice and driving it with a goad. Some of the wild breed, though by far the strongest, are yet very

refractory, and often turn upon their drivers—who have then no other resource but to cover themselves with their sledge, and let the animal vent its fury upon that. But it is otherwise with those that are tame; no creature can be more active, patient, and willing. When hard pushed they will trot nine or ten Swedish (or between fifty and sixty English) miles at one stretch; but in such a case the poor obedient creature fatigues itself to death, and, if not prevented by the Laplander, who kills it immediately, it would die in a day or two after. In general they can go about thirty miles without halting, and this without any great or dangerous efforts. This, which is the only manner of travelling in that country, can be performed only in winter, when the snow is glazed over with ice; and although it is a very speedy method of conveyance, yet it is inconvenient, dangerous, and troublesome.

In order to make these animals more obedient and more generally serviceable, they castrate them. This operation the Laplanders perform with their teeth; these become sooner fat when taken from labour, and they are found to be stronger when drawing the sledge. They usually leave one entire male to every six females; these are in rut from the Feast of St. Matthew to about Michaelmas. At this time their horns are thoroughly burnished, and their battles among each other are fierce and obstinate. The females do not begin to breed till they are two years old; and then they continue regularly breeding every year until they are superannuated. They go with young above eight months, and generally bring forth two at a time. The fondness of the dam for her young is very remarkable; it often happens that when they are separated from her she will return from pasture, keep calling round the cottage for them, and will not desist until, dead or alive, they are brought and laid at her feet. They are at first of a light brown; but they become darker with age, and at last the old ones are of a brown almost approaching to blackness. The young follow the dam for two or three years; but they do not acquire their full growth until four. They are then broke in, and managed for drawing the sledge; and they continue serviceable for four or five years longer. They never live above fifteen or sixteen years; and when they arrive at the proper age the Laplander generally kills them for the sake of their skins and their flesh. This he performs by striking them on the back of the neck with his knife into the spinal marrow; upon which they instantly fall, and he then cuts the arteries that lead to the heart, and lets the blood discharge itself into the cavity of the breast.

There is scarce any part of this animal that is not converted to its peculiar uses. As soon as it begins to grow old, and some time before the rut, it is killed, and the flesh dried in the air. It is also sometimes dried and hardened with smoke, and laid up for travelling provision when the natives migrate from one part of the country to another. During the winter the rein-deer are slaughtered as are sheep with us; and every four persons in a family are allowed one rein-deer for their week's subsistence. In spring they spare the hard as much as they can, and live upon fresh fish. In summer the milk and curd of the rein-deer makes their chief provision; and in autumn they live wholly upon fowls, which they kill with a cross-bow or catch in springes. Nor is this so scanty an allowance, since at that time the sea-fowls come in such abundance that their ponds and springs are covered over. These are not so shy as with us, but yield themselves an easy prey. They are chiefly allured to these places by the swarms of geese which infest the country during summer, and now repay the former inconveniences, by inviting such numbers of birds as supply the natives with food a fourth part of the year.

The milk when newly taken is warmed in a cauldron and thickened with rennet; and then the curd is pressed

into cheese, which are small and well tasted: These are never found to breed mites, as is the case with cheeses of other countries—probably because the mite-fly is not to be found in Lapland. The whey which remains is warmed up again, and becomes of a consistence as if thickened with the white of an egg. Upon this the Laplanders feed during the summer: it is pleasant and well tasted, but not very nourishing. As to butter, they seldom make any, because the milk affords but a very small quantity, and this both in taste and consistence more nearly resembles suet. They never keep their milk till it turns sour, and do not dress it into the different sorts of dishes which the more southern countries are known to do. The only delicacy they make from it is with wood-sorrel, which, being boiled up with it and then left to coagulate, the whole is put into casks or deer-skins, and kept under ground to be consumed in winter.

The skin is even a more valuable part of this animal than either of the former. From that part of it which covered the head and feet they make their strong snow-shoes, with the hair on the outside. Of the other parts they compose their garments, which are extremely warm, and which cover them all over. The hair of these also is on the outside; and they sometimes line them with the fur of the glutton, or some other warm-furred animal of that climate. These skins also serve them for beds. They spread them on each side of the fire, upon some leaves of the dwarf birch-tree, and in this manner lie both soft and warm. Many garments made of the skin of the rein-deer are sold every year to the inhabitants of the more southern parts of Europe; and they are found so serviceable in keeping out the cold, that even people of the first rank are known to wear them.

In short, no part of this animal is thrown away as useless. The blood is preserved in small casks, to make sauce with the marrow in spring; the horns are sold to be converted into glue; the sinews are dried, and divided so as to make the strongest kind of sewing thread, not unlike catgut; the tongues, which are considered as a great delicacy, are dried, and sold into the more southern provinces; the intestines themselves are washed like our tripe, and in high esteem among the natives. Thus the Laplander finds all his necessities amply supplied from this single animal; and he who has a large herd of these animals has no idea of higher luxury.

But although the rein-deer be a very hardy and vigorous animal, it is not without its diseases. I have already mentioned the pain it feels from the gnat, and the apprehensions it is under from the gadfly. Its hide is often found pierced in a hundred places like a sieve from this insect, and not a few die in their third year from this very cause. Their teats, also, are subject to cracking, so that blood comes instead of milk. They sometimes take a loathing for their food; and, instead of eating, stand still and chew the cud. They are also troubled with a vertigo, like the elk, and turn round often till they die. The Laplander judges of their state by the manner of their turning: if they turn to the right, he judges their disorder but slight; if they turn to the left, he deems it insurable. The rein-deer are also subject to ulcers near the hoof, which unqualifies them for travelling or keeping with the herd. But the most fatal disorder of all is that which the natives call the "sud-dakka," which attacks this animal at all seasons of the year. The instant it is seized with this disease it begins to breathe with great difficulty; its eyes begin to stare and its nostrils to expand. It acquires also an unusual degree of ferocity, and attacks all it meets indiscriminately. Still, however, it continues to feed as if in health, but is not seen to chew the cud, and it lies down more frequently than before. In this manner it continues, every day consuming and growing more lean, till at last

it dies from mere inanition; and not one of these that are attacked with this disorder are ever found to recover. Notwithstanding, it is but very lately known in that part of the world; although, during the last ten or fifteen years it has spoiled whole provinces of this necessary creature. It is contagious: and the moment the Laplander perceives any of his herd infected he hastens to kill them immediately before it spreads any farther. When examined internally, there is a frothy substance found in the brain and round the lungs; the intestines are lax and flabby, and the spleen is diminished almost to nothing. The Laplander's only cure in all these disorders is to anoint the animal's back with tar; if this does not succeed, he considers the disease as beyond the power of art; and, with his natural phlegm, submits to the severities of Fortune.

Besides the internal maladies of this animal, there are some external enemies which it has to fear. The bears now and then make depredations upon the herd; but of all their persecutors, that ravenous creature called the "glutton" is the most dangerous and the most successful. The war between these is carried on not less in Lapland than in North America, where the rein-deer is called the "caribou," and the glutton the "carcajou." This animal, which is not above the size of the badger, waits whole weeks together for its prey, concealed in the branches of some spreading tree; and when the wild rein-deer passes underneath it suddenly drops down upon it, fixing its teeth and claws into the neck immediately behind the horns. It is in vain that the wounded animal then flies for protection—that it rustles among the branches of the forest; the glutton still holds its former position, and, although it often loses a part of its skin and flesh, which are rubbed off against the trees, yet it still keeps fast, until its victim drops with fatigue and loss of blood. The deer has but one only method of escape, which is by jumping into the water. That element its enemy cannot endure; for, as we are told, it quits its hold immediately, and then thinks only of providing for its own personal security.

## QUADRUPEDS OF THE HOG KIND.

### BOOK III.—CHAP. I.

INTRODUCTION.—Animals of the hog kind seem to unite in themselves all those distinctions by which others are separated. They resemble those of the horse kind in the number of their teeth (which in all amount to forty-four), in the length of their head, and in having but a single stomach. They resemble the cow kind in their cloven hoofs and the position of their intestines; and they resemble those of the claw-footed kind in their appetite for flesh, in their not chewing the cud, and in their numerous progeny. Thus this species serves to fill up that chasm which is found between the carnivorous kinds and those that live upon grass—being possessed of the ravenous appetite of the one and the inoffensive nature of the other. We may consider them, therefore, as of a middle nature, which we can refer neither to the rapacious nor the peaceful kinds, and yet partaking somewhat of the nature of both. Like the rapacious kinds, they are found to have short intestines; their hoofs, also, though cloven to the sight, will, upon anatomical inspection, appear to be supplied with bones like beasts of prey; and the number of their teats also increase the similitude; on the other hand, in a natural state they live upon vegetables, and seldom seek after animal food except when urged by necessity. They offend no other animal of the forest, at the same time they are furnished with arms to terrify the bravest.

**THE WILD BOAR.**—This is the original of the many varieties we find in this creature, and is by no means so stupid nor so filthy an animal as that we have reduced to tameness; he is much smaller than the tame hog, and does not vary in his colour as those of the domestic kind do, but is always found of an iron grey, inclining to black; his snout is much longer than that of the tame hog, and the ears are shorter, rounder, and black; of which colour are also the feet and the tail. He roots the ground in a different manner from the common hog; for as this turns up the earth in little spots here and there, so the wild boar ploughs it up like a furrow, and does irreparable damage in the cultivated lands of the farmer. The tusks, also, of this animal are larger than in the tame breed, some of them being seen almost a foot long. These, as is well known, grow from both the under and upper jaw, bent upwards circularly, and are exceedingly sharp at the points. They differ from the tusks of the elephant in this, that they never fall; and it is remarkable of all the hog kind that they never shed their teeth as other animals are seen to do. The tusks of the lower jaw are always most to be dreaded, and are found to give very terrible wounds.

The wild boar can properly be called neither a solitary nor a gregarious animal. The three first years the whole litter follows the sow, and the family lives in a herd together. They are then called beasts of company, and unite their common forces against the invasions of the wolf or the more formidable beasts of prey. Upon this their principal safety while young depends, for when attacked they give each other mutual assistance, calling to each other with a very loud and fierce note; the strongest face the danger; they form a ring, and the weakest fall into the centre. In this position few ravenous beasts dare venture to attack them, but pursue the chase where there is less resistance and danger. However, when the wild boar is come to a state of maturity, and when conscious of his own superior strength, he then walks the forest alone and fearless. At that time he dreads no single creature, nor does he turn out of his way even for man himself. He does not seek danger, and he does not much seem to avoid it.

This animal is therefore seldom attacked but at a disadvantage, either by numbers or when sound sleeping by moonlight. The hunting the wild boar is one of the principal amusements of the nobility in those countries where it is to be found. The dogs provided for this sport are of the slow, heavy kind. Those used for hunting the stag or the roebuck would be very improper, as they would too soon come up with their prey, and, instead of a chase, would only furnish out an engagement. A small mastiff is therefore chosen; nor are the hunters much mindful of the goodness of their nose, as the wild boar leaves so strong a scent that it is impossible for them to mistake its course. They never hunt any but the largest and the oldest, which are known by their tracks. When the boar is "reared," as is the expression for driving him from his covert, he goes slowly and uniformly forward, not much afraid, nor very far before his pursuers. At the end of every half mile or thereabouts he turns round, stops till the hounds come up, and offers to attack them. These, on the other hand, knowing their danger, keep off, and bay him at a distance. After they have for a while gazed upon each other with mutual animosity, the boar again slowly goes on his course and the dogs renew their pursuit. In this manner the chase is sustained, and the chase continues till the boar is quite tired and refuses to go any farther. The dogs then attempt to close in upon him from behind; those which are young, fierce, and unaccustomed to the chase, are generally the foremost, and often lose their lives by their ardour. Those which are older and better trained are content to wait until the hunters come up, who strike at him with their spears, and, after several blows, despatch or disable him. The instant the animal is killed they

cut off the testicles, which would otherwise give a taint to the flesh; and the huntsmen celebrate their victory with their horns.

**THE HOG,** in a natural state, is found to feed chiefly upon roots and vegetables; it seldom attacks any other animal, being content with such provisions as it procures without danger. Whatever animal happens to die in the forest, or is so wounded that it can make no resistance, becomes a prey to the hog, who seldom refuses animal food, how putrid soever, although it is never at the pains of taking or procuring it alive. For this reason it seems a glutton rather by accident than choice, content with vegetable food, and only devouring flesh when pressed by necessity and when it happens to offer. Indeed, if we behold the hog in its domestic state it is the most sordid and brutal animal in Nature. The awkwardness of its form seems to influence its appetites, and all its sensations are as gross as its shapes are unsightly. It seems possessed only of an insatiable desire of eating, and seems to make choice only of what other animals find the most offensive. But we ought to consider that the hog with us is in an unnatural state, and that it is compelled to feed in this filthy manner from wanting that proper nourishment which it finds in the forest. When in a state of wildness it is of all other quadrupeds the most delicate in the choice of what vegetables it shall feed on, and rejects a greater number than any of the rest. The cow, for instance, as we are assured by Linnaeus, eats two hundred and seventy-six plants, and rejects two hundred and eighteen; the goat eats four hundred and forty-nine, and rejects a hundred and twenty-six; the sheep eats three hundred and eighty-seven, and rejects a hundred and forty-one; the horse eats two hundred and sixty-two, and rejects two hundred and twelve; but the hog, more nice in its provision than any of the former, eats but seventy-two plants, and rejects a hundred and seventy-one. The indecacy of this animal is, therefore, rather in our apprehensions than in its nature, since we find it makes a very distinguishing choice in the quality of its food; and if it does not reject animal putrefaction, it may be because it is abridged in that food which is most wholesome and agreeable to it in a state of nature. This is certain, that its palate is not insensible to the difference of eatables; for where it finds variety it will reject the worst with as distinguishing a taste as any other quadruped whatsoever. In the orchards of peach-trees in North America, where the hog has plenty of delicious food, it is observed that it will reject the fruit that has lain but a few hours on the ground, and continue on the watch whole hours together for a fresh supply.

However, the hog is naturally formed in a more imperfect manner than the other animals that we have rendered domestic around us—less active in its motions, less furnished with instinct in knowing what to pursue or avoid. Without attachment, and incapable of instruction, it continues while it lives an useless, or rather a rapacious dependent. The coarseness of its skin and the thickness of its hide, together with the thick coat of fat which lies immediately under the skin, render it insensible to blows or rough usage. Mice have been known to burrow in the back of these animals while fattening in the sty, without their seeming to perceive it. Their other senses seem to be in tolerable perfection; they scent the hounds at a distance; and, as we have seen, they are not insensible in the choice of their provisions.

The hog is by nature stupid, inactive, and drowsy; if undisturbed it would sleep half its time; but it is frequently awakened by the calls of appetite, which when it has satisfied it goes to rest again. Its whole life is thus a round of sleep and gluttony; and if supplied with sufficient food it soon grows unfit even for its own existence; its flesh becomes a greater load than its legs

are able to support, and it continues to feed lying down or kneeling—a helpless instance of indulged sensuality. The only time it seems to have passions of a more active nature are when it is incited by venery, or when the wind blows with any vehemence. Upon this occasion it is so agitated as to run violently towards its sty, screaming horribly at the same time, which seems to argue that it is naturally fond of a warm climate. It appears also to foresee the approach of bad weather, bringing straw to its sty in its mouth, preparing a bed, and hiding itself from the impending storm. Nor is it less agitated when it hears any of its kind in distress: when a hog is caught in a gate, as is often the case, or when it suffers any of the usual domestic operations of ringing or spaying, all the rest are then seen to gather round it, to lend their fruitless assistance, and to sympathise with its sufferings. They have often also been known to gather round a dog that had teased them, and kill him on the spot.

Most of the diseases of this animal arise from intemperance; measles, imposthumes, and scrofulous swellings are reckoned among the number. It is thought by some that they wallow in the mire to destroy a sort of louse or insect that is often found to infest them; however, they are generally known to live when so permitted to eighteen or twenty years; and the females produce till the age of fifteen. As they produce from ten to twenty young at a litter, and that twice a-year, we may easily compute how numerous they would shortly become if not diminished by human industry. In the wild state they are less prolific; and the sow of the woods brings forth but once a-year, probably because exhausted by rearing up her former numerous progeny.

It would be superfluous to dwell longer upon the nature and qualities of an animal too well known to need a description; there are few, even in cities, who are unacquainted with its uses, its appetites, and way of living. The arts of fattening, rearing, guarding, and managing hogs fall more properly under the cognizance of the farmer than the naturalist; they make a branch of domestic economy, which, properly treated, may be extended to a great length; but the history of Nature ought always to end where that of Art begins. It will be sufficient, therefore, to observe that the wild boar was formerly a native of our country, as appears from the laws of Hoeldda, the famous Welch legislator, who permitted his grand huntsman to chase that animal from the middle of November to the beginning of December. William the Conqueror also punished such as were convicted of killing the wild boar in his forests with the loss of their eyes. At present the whole wild breed is extinct; but no country makes greater use of the tame kinds, as their flesh, which bears salt better than that of any other animal, makes a principal part of the provisions of the British navy.

As this animal is a native of almost every country, there are some varieties found in the species. That which we call the East India breed is lower, less furnished with hair, is usually black, and has the belly almost touching the ground; it is now common in England; it fattens more easily than the ordinary kinds, and makes better bacon.

There is a remarkable variety of this animal about Upsal, which is single hoofed like the horse; but in no other respect differing from the common kinds. The authority of Aristotle, who first made mention of this kind, has been often called into question; some have asserted that such a quadruped never existed, because it happened not to fall within the sphere of their own confined observation; however, at present the animal is too well known to admit of any doubt concerning it. The hog common in Guinea differs also in some things from our own; though shaped exactly as ours, it is of a reddish colour, with long ears, which end in a sharp point, and a tail which hangs down to the pastern; the whole

body is covered with short and shining hair, without any bristles, but pretty long near the tail. Their flesh is said to be excellent, and they are very tame.

All these, from their near resemblance to the hog, may be considered as of the same species; the East Indian hog, we well know, breeds with the common kind; whether the same obtains between it and those of Upsal and Guinea we cannot directly affirm; but where the external similitude is so strong we may be induced to believe that the appetites and habits are the same. It is true, we are told that the Guinea breed will not mix with ours, but keep separate, and herd only together: however, this is no proof of their diversity, since every animal will prefer its own likeness in its mate; and they will only then mix with another sort when deprived of the society of their own. These, therefore, we may consider as all of the hog kind; but there are other quadrupeds that in general resemble this species, which nevertheless are very distinct from them. Travellers, indeed, from their general form or from their habits and way of living, have been content to call these creatures hogs also; but upon a closer inspection their differences are found to be such as entirely to separate the kinds, and make each a distinct animal by itself.

## CHAP. II.

### THE PECCARY, OR TAJUCA.

That animal which of all others most resembles the hog, and yet is of a formation very distinct from it, is called the "peccary," or "tajuca." It is a native of America, and found there in such numbers that they are seen in herds of several hundreds together, grazing among the woods, and harmless except when offended.

The peccary at first view resembles a small hog; the form of its body, the shape of its head, the length of its snout, and the form of its legs are exactly alike: however, when we come to examine it nearer the differences begin to appear. The body is not so bulky—its legs not so long—its bristles much thicker and stronger than those of the hog, resembling rather the quills of a porcupine than hair; instead of a tail, it has only a small fleshy protuberance, which does not even cover its posterior; but that which is still more extraordinary, and in which it differs from all other quadrupeds, is, that it has got upon its back a lump resembling the navel in other animals, which is found to separate a liquor of a very strong smell. The peccary is the only creature that has those kind of glands which discharge the musky substance on that part of its body. Some have them under the belly, and others under the tail; but this creature, by a conformation peculiar to itself, has them on its back. This lump or navel is situated on that part of the back which is over the hinder legs; it is in general so covered with long bristles that it cannot be seen, except they be drawn aside. A small space then appears which is almost bare, and only beset with a few short fine hairs. In the middle it rises like a lump; and in this there is an orifice into which one may thrust a common goose-quill. This hole or bag is not above an inch in depth; and round it, under the skin, are situated a number of small glands, which distil a whitish liquor, in colour and substance resembling that obtained from the civet. Perhaps it was this analogy which led Dr. Tyson to say that it smelt agreeably, also, like that perfume. But this Mr. Buffon absolutely denies, affirming that the smell is at every time and in every proportion strong and offensive;—and to this I can add my own testimony, if that able naturalist should want a voucher.

But to be more particular in the description of the other parts of this quadruped—the colour of the body is

grizzly, and beset with bristles thicker and stronger than those of a common hog; though not near so thick as those of the porcupine, they resemble them in this respect—they are variegated with black and white rings. The belly is almost bare; and the short bristles on the sides gradually increase in length as they approach the ridge of the back, where some are five inches long. On the head, also, between the ears, there is a large tuft of bristles, which are chiefly black. The ears are about two inches and a half long, and stand upright; and the eyes resemble those of a common hog, only they are smaller. From the lower corner of the eye to the snout is usually six inches; and the snout itself is like that of a hog's, though it is but small. One side of the lower lip is generally smooth, by the rubbing of the tusk of the upper jaw. The feet and hoofs are perfectly like those of a common hog; but, as has been previously observed, it has no tail. There are some anatomical differences in its internal structure from that of the common hog. Dr. Tyson was led to suppose that it had three stomachs, whereas the hog has but one; however, in this he was deceived, as Mr. Daubeton has plainly shown that the stomach is only divided by two closings, which give it the appearance as if divided into three; and there is no conformation that prevents the food in any part of it from going or returning to any other.

The peccary may be tamed like the hog, and has much the same habits and natural inclinations. It feeds upon the same aliments; its flesh, though drier and leaner than that of the hog, is pretty good eating; it is improved by castration; and, when killed, not only the parts of generation must be instantly taken away, but also the navel on the back, with all the glands that contribute to its supply. If this operation be deferred for only half an hour the flesh becomes utterly unfit to be eaten.

The peccary is extremely numerous in all the parts of Southern America. They go in herds of two or three hundred together, and unite, like hogs, in each other's defence. They are particularly fierce when their young are attempted to be taken from them. They surround the plunderer, attack him without fear, and frequently make his life pay the forfeit of his rashness. When any of the natives are pursued by a herd in this manner, they frequently climb a tree to avoid them; while the peccaries gather round the root, threaten with their tusks, and, their rough bristles standing erect as in the hog kind, they assume a very terrible appearance. In this manner they remain at the foot of the tree for hours together; while the hunter is obliged to wait patiently, and not without apprehensions, until they think fit to retire.

The peccary is more fond of the mountainous parts of the country than the lowlands; it seems to delight neither in the marshes nor the mud like our hogs; it keeps among the woods, where it subsists upon wild fruits, roots, and vegetables; it is also an unceasing enemy to the lizard, the toad, and all the serpent kinds with which these uncultivated forests abound. As soon as it perceives a serpent or a viper it at once seizes it with its fore-hoofs and teeth, skins it in an instant, and devours its flesh. This is often seen, and may therefore be readily credited; but as to its applying to a proper vegetable immediately after, as an antidote to the poison of the animal it had devoured, this part of the relation we may very well suspect. The flesh neither of the toad nor viper, as every one now knows, is poisonous; and therefore there is no need of a remedy against their venom. Ray gives no credit to either part of the account; however, we can have no reason to disbelieve that it feeds upon toads and serpents; it is only the making use of a vegetable antidote that appears improbable, and which, perhaps, had its rise in the ignorance and credulity of the natives.

The peccary, like the hog, is very prolific; the young

ones follow the dam, and do not separate until they have come to perfection. If taken at first they are very easily tamed, and soon lose all their natural ferocity; however, they never show any particular signs of docility, but continue stupid and rude, without attachment, or even seeming to know the hand that feeds them. They only continue to do no mischief; and they may be permitted to run tame without apprehending any dangerous consequences. They seldom stray far from home; they return of themselves to the sty, and do not quarrel among each other except when they happen to be fed in common. At such times they have an angry kind of growl, much stronger and harsher than that of a hog; but they are seldom heard to scream like the former; only now and then, when frightened or irritated, they have an abrupt, angry manner of blowing like the boar.

The peccary, though like the hog in so many various respects, is nevertheless quite a distinct race, and will not mix, nor produce an intermediate breed. The European hog has been transplanted into America, and suffered to run wild among the woods; it is often seen to herd among a drove of peccaries, but never to breed from them. They may therefore be considered as two distinct creatures; the hog is the larger and the more useful animal—the peccary more feeble and local; the hog subsists in most parts of the world, and in almost every climate—the peccary is a native of the warmer regions, and cannot subsist in ours without shelter and assistance. It is more than probable, however, that we could readily propagate the breed of this quadruped, and that in two or three generations it might be familiarised to our climate: but as it is inferior to the hog in every respect, so it would be needless to admit a new domestic whose services are better supplied in the old.

### CHAP. III.

#### THE CAPIBARA, OR CABIAL.

There are some quadrupeds so entirely different from any that we are acquainted with, that it is hard to find a well-known animal to which to resemble them. In this case we must be content to place them near such as they most approach in form and habits, so that the reader may at once have some idea of the creature's shape or disposition, although, perhaps, an inadequate and very confused one.

Upon that confused idea, however, it will be our business to work—to bring it by degrees to greater precision—to mark out the differences of form; and thus give the clearest notions that words can easily convey. The known animal is a kind of rude sketch of the figure we want to exhibit, from which by degrees we fashion out the shape of the creature we desire should be known—as a statuary seldom begins his work till the rude outline of the figure is given by some other hand. In this manner I have placed the capibara among the hog kind, merely because it is more like a hog than any other animal commonly known; and yet, more closely examined, it will be found to differ in some of the most obvious particulars.

The capibara resembles a hog of about two years old in the shape of its body and the coarseness and colour of its hair. Like the hog, it has a thick short neck and a rounded bristly back; like the hog, it is partial to the water and marshy places, brings forth many at a time, and, like it, feeds upon animal and vegetable food. But when examined more nearly the differences are many and obvious. The head is longer, the eyes are larger, and the snout, instead of being rounded as in the hog, is split like that of a rabbit or a hare, and furnished with thick strong whiskers; the mouth is not so wide; the number and the form of the teeth are different—~~the~~

it is without tusks: like the peccary it wants a tail; and, unlike to all others of this kind, instead of a cloven hoof it is in a manner web-footed, and thus entirely fitted for swimming and living in the water. The hoofs before are divided into four parts, and those behind into three; between the divisions there is a prolongation of the skin, so that the foot when spread in swimming can beat a great surface of water.

As its feet are thus made for the water, so it is seen to delight entirely in that element; and for that reason some naturalists have called it the "water-hog." It is a native of South America, and is chiefly seen frequenting the borders of lakes and rivers, like the otter. It seizes the fish upon which it preys with its hoofs and teeth, and carries them to the edge of the lake to devour them at its ease. It also lives upon fruits, corn, and sugar-canes. As its feet are long and broad, it is often seen sitting up like a dog that is taught to beg. Its cry more nearly resembles the braying of an ass than the grunting of a hog. It seldom goes out except at night, and that always in company. It never ventures far from the sides of the river or the lake in which it preys; for as it runs ill, owing to the length of its feet and the shortness of its legs, so its only place of safety is the water, into which it immediately plunges when pursued, and keeps so long at the bottom that the hunter can have no hopes of taking it there. The capibara, even in a state of wildness, is of a gentle nature, and when taken young is easily tamed. It comes and goes at command, and even shows an attachment to its keeper. Its flesh is said to be fat and tender, but from the nature of its food it has a fishy taste, like all those which are bred in the water. Its head, however, is said to be excellent; and in this it resembles the beaver, whose fore parts taste like flesh, and the hinder parts like the fish it feeds upon.

#### CHAP. IV.

##### THE BABYROUESA, OR INDIAN HOG.

The babyrouessa is still more remote from the hog kind than the capibara; and yet most travellers who have described this animal do not scruple to call it the hog of Borneo, which is an island in the East Indies, where it is principally to be found. Probably this animal's figure upon the whole most resembles that of the hog kind, which may have induced them to rank it among the number; however, when they come to its description they represent it as having neither the hair, the bristles, the head, the stature, nor the tail of a hog. Its legs, we are told, are longer, its snout shorter, its body more slender, and somewhat resembling that of a stag; its hair is finer, of a grey colour, more resembling wool than bristles, and its tail also tufted with the same. From these varieties, therefore, it can scarcely be called a hog; and yet in this class we must be content to rank it until its form and nature are better known. What we at present principally distinguish it by are four enormous tusks that grow out of each jaw—the two largest from the upper and the two smallest from the under. The jaw-bones of this extraordinary animal are found to be very thick and strong; from whence these monstrous tusks are seen to proceed that distinguish it from all other quadrupeds. The two that go from the lower jaw are not above a foot long, but those of the upper are above half a yard: as in the boar, they bend circularly, and the two lower stand in the jaw as they are seen to do in that animal; but the two upper ones rise from the upper jaw rather like horns than teeth, and, bending upwards and backwards, sometimes have their points directed to the animal's eyes, and often prove fatal by growing into them. Were it not that the

babyrouessa has two such large teeth underneath, we might easily suppose the two upper ones to be horns; in fact, their sockets are directed upwards, for which reason Dr. Grew was of that opinion. But as the teeth of both jaws are of the same consistence, and as they both grow out of sockets in the same manner, the analogy between both is too strong not to suppose them of the same nature. The upper teeth when they leave the socket immediately pierce the upper lips of the animal, and grow as if they immediately went from his cheek. The tusks in both jaws are of a very fine ivory, smoother and whiter than that of the elephant, but not so hard or serviceable.

These enormous tusks give this animal a formidable appearance; and yet it is thought to be less dangerous than the wild boar. Like animals of the hog kind, they go together in a body, and are often seen in company with the wild boar, with which, however, they are never known to engender. They have a very strong smell, which discovers them to the hounds; and when pursued they growl dreadfully, often turning back upon the dogs, and wounding with the tusks of the lower jaw—for the upper tusks are rather an obstruction than a defence. They run much swifter than the boar, and have a more exquisite scent, winding the men and the dogs at a great distance. When hunted closely they generally plunge into the sea, where they swim with great swiftness and facility, diving and rising again at pleasure; and in this manner they most frequently escape their pursuers. Although fierce and terrible when offended, yet they are peaceable and harmless when unmolested. They are easily tamed, and their flesh is good to be eaten; but it is said to putrefy in a very short time. They have a way of reposing themselves different from most other animals of the larger kind—which is by hitching one of their upper tusks on the branch of a tree, and then suffering their whole body to swing down at ease. Thus suspended by a tooth, they continue the whole night quite secure, and out of the reach of such animals as hunt them for prey.

The babyrouessa, though by its teeth and tusks it seems fitted for a state of hostility, and probably is carnivorous, yet nevertheless seems chiefly to live upon vegetables and the leaves of trees. It seldom seeks to break into gardens, like the boar, in order to pillage the more succulent productions of human industry, but lives remote from mankind, content with coarser fare and security. It has been said that the babyrouessa was only to be found in the island of Borneo; but this is a mistake, as it is well known in many parts both of Asia and Africa, as at the Celebes, at Estrila, Senegal, and Madagascar.

Such are the animals of the hog kind which are not distinctly known; and even all these, as we see, have been but imperfectly examined or described. There are some others of which we have still more imperfect notices—such as the wares, a hog of the Isthmus of Darien, described by Wasser, with large tusks, small ears, and bristles like a coarse fur over all the body. This, however, may be the European hog, which has run wild in that part of the new world, as no other traveller has taken notice of the same. The Canary boar seems different from other animals of this kind by the largeness of its tusks, and, as is judged from the skeleton, by the aperture of its nostrils and the number of its grinders. I cannot conclude this account of those animals that are thus furnished with enormous tusks without observing that there is a strong consent between these and the parts of generation. When castrated the tusks grow much smaller, and are scarce seen to appear without the lips; but what is still more remarkable is, that in a boar, if the tusks by any accident or design be broke away, the animal abates of its fierceness and venery, and it produces nearly the same effect upon its constitution as if castration had actually taken place.

## CARNIVOROUS ANIMALS.

## BOOK IV.—CHAP. I.

## ANIMALS OF THE CAT KIND.

We have hitherto been describing a class of peaceful and harmless animals that serve as the instruments of man's happiness, or at least that do not openly oppose him. We come now to a bloody and unrelenting tribe, that disdain to own his power, and carry on unceasing hostilities against him. All the class of the cat kind are chiefly distinguished by their sharp and formidable claws, which they can hide and extend at pleasure. They lead a solitary, ravenous life, neither uniting for their mutual defence, like vegetable feeders, nor for their mutual support, like those of the dog kind. The whole of this cruel and ferocious tribe seek their food alone; and, except at certain seasons, are even enemies to each other. The dog, the wolf, and the bear are sometimes known to live upon vegetable or farinaceous food; but all of the cat kind—such as the lion, the tiger, the leopard, and the ounce—devour nothing but flesh, and starve upon any other provision.

They are in general fierce, rapacious, subtle, and cruel—unfit for society among each other, and incapable of adding to human happiness. However, it is probable that even the fiercest could be rendered domestic if man thought the conquest worth the trouble. Lions have been yoked to the chariots of conquerors; and tigers have been taught to tend those herds which they are known at present to destroy. But these services are not sufficient to recompense for the trouble of their keeping; so that ceasing to be useful they continue to be noxious, and become rebellious subjects because not taken under equal protection with the rest of the brute creation.

Other tribes of animals are classed with difficulty, having often but few points of resemblance, and, though alike in form, have different dispositions and different appetites. But all those of the cat kind, although differing in size or in colour, are yet nearly allied to each other—being equally fierce, rapacious, and artful; and he that has seen one has seen all. In other creatures there are many changes wrought by human assiduity; the dog, the hog, or the sheep are altered in their natures and forms, just as the necessities or caprice of mankind have found fitting; but all of this kind are inflexible in their forms, and wear the print of their natural wildness strong upon them. The dogs or cows vary in different countries, but lions or tigers are still found the same; the very colour is nearly alike in all; and the slightest alterations are sufficient to make a difference in the kinds, and to give the animal a different denomination.

The cat kind are not less remarkable for the sharpness and strength of their claws, which are thrust forth from their sheath when they seize their prey, than for the shortness of their snout, the roundness of their head, and the large whiskers which grow on the upper lip. Their teeth, also, which amount to the number of thirty, are very formidable, but are rather calculated for tearing their prey than for chewing it; for this reason they feed but slowly; and while they eat they generally continue growling, to deter others from taking a share. In the dog kind the chief power lies in the under jaw, which is long, and furnished with muscles of amazing strength; but in these the greatest force lies in the claws, which are extended with great ease, and their gripe is so tenacious that nothing can open it. The hinder parts in all these animals are much weaker than those before; and they seem less made for strength than agility. Nor are they endued with the swiftness of most other animals, but generally owe their subsistence rather to catching their prey by surprise than by hunting it fairly down. They all seize it with a bound, at the same time express-

ing their fierce pleasure with a roar; and the first grasp generally disables the captive from all further resistance. With all these qualifications for slaughter, they nevertheless seem timid and cowardly, and seldom make an attack, like those of the dog kind, at a disadvantage; on the contrary, they fly when the force against them is superior, or even equal with their own; and the lion himself will not venture to make a second attack where he has been once repulsed with success. For this reason, in countries that are tolerably inhabited the lion is so cowardly, that he is often scared away by the cries of women and children.

The cat, which is the smallest animal of this kind, is the only one that has been taken under human protection, and may be considered as a faithless friend brought to oppose a still more insidious enemy. It is, in fact, the only animal of this tribe whose services can more than recompense the trouble of their education, and whose strength is not sufficient to make its anger formidable. The lion or the tiger may easily be tamed and rendered subservient to human command; but even in their humblest and most familiar moments they are still dangerous; since their strength is such that the smallest fit of anger or caprice may have dreadful consequences. But the cat, though easily offended and often capricious in her resentments, is not endowed with powers sufficient to do any great mischief. Of all animals, when young, there is none more prettily playful than the kitten; but it seems to lose this disposition as it grows old, and the innate treachery of its kind is then seen to prevail. From being naturally ravenous, education teaches it to disguise its appetites, and to watch the favourable moment of plunder; supple, insinuating, and artful, it has learned the arts of concealing its intentions till it can put them into execution; when the opportunity offers it at once seizes upon whatever it finds, flies off with it, and continues at a distance till it supposes its offence forgotten. The cat has only the appearance of attachment; and it may easily be perceived, by its timid approaches and side long looks, that it either dreads its master or distrusts his kindness; different from the dog, whose caresses are sincere, the cat is assiduous rather for its own pleasure than to please, and often gains confidence only to abuse it. The form of its body and its temperament correspond with its disposition; active, cleanly, delicate, and voluptuous, it loves its ease, and seeks the softest cushions to lie on. Many of its habits, however, are rather the consequences of its formation than the result of any perverseness in its disposition; it is timid and mistrustful, because its body is weak and its skin tender; a blow hurts it infinitely more than it does a dog, whose hide is thick and body muscular; the long fur in which the cat is clothed entirely disguises its shape, which, if seen naked, is long, feeble, and slender; it is not to be wondered, therefore, that it appears much more fearful of chastisement than the dog, and often flies even when no correction is intended. Being also a native of the warmer climates (as will be shown hereafter), it chooses the softest bed to lie on, which is always the warmest.

The cat goes with young fifty-six days, and seldom brings forth above five or six at a time. The female usually hides the place of her retreat from the male, who is often found to devour her kittens. She feeds them for some weeks with her milk, and whatever small animal she can take by surprise, accustoming them betimes to rapine. Before they are a year old they are fit to engender; the female seeks the male with cries; nor is their copulation performed without great pain, from the narrowness of the passage in the female. They live to about the age of ten years; and during that period they are extremely vivacious, suffering to be worried a long time before they die.

The young kittens are very playful and amusing; but their sport soon turns into malice, and they from the

beginning show a disposition to cruelty; they often look winfully towards the cage, sit centinels at the mouth of a mouse-hole, and in a short time become more expert hunters than if they had received the instructions of art. Indeed, their disposition is so incapable of constraint that all instruction would be but thrown away. It is true, that we are told of the Greek monks of the isle of Cyprus teaching cats to hunt the serpents with which the island is infested; but this may be natural to the animal itself, and they might have fallen upon such a pursuit without any instruction. Whatever animal is much weaker than themselves is to them an indiscriminate object of destruction. Birds, young rabbits, hares, rats and mice, bats, moles, toads, and frogs, are all equally pursued—though not, perhaps, equally acceptable. The mouse seems to be their favourite game; and, although the cat has the sense of smelling in but a mean degree, it nevertheless knows those holes in which its prey resides. I have seen one of them patiently watch a whole day until the mouse appeared, and continue quite motionless until it came within reach, and then seized it with a jump. Of all the marks by which the cat discovers its natural malignity, that of playing and sporting with its little captive before killing it outright is the most flagrant.

The fixed inclination which they discover for this peculiar manner of pursuit arises from the conformation of their eyes. The pupil in man, and in most other animals, is capable but of a small degree of contraction and dilatation; it enlarges a little in the dark, and contracts when the light pours in upon it in too great quantities. In the eyes of cats, however, this contraction and dilatation of the pupil is so considerable, that the pupil, which appears narrow and small like the black of one's nail, by night expands over the whole surface of the eye-ball, and, as every one must have seen, their eyes seem on fire. By this peculiar conformation their eyes see better in darkness than light, and the animal is thus better adapted for spying out and surprising its prey.

Although the cat is an inhabitant of our houses, yet it cannot properly be called a dependent: although perfectly tame, yet it acknowledges no obedience; on the contrary, it does only just what it thinks fit, and no art can controul any of its inclinations. In general it is but half tamed, and has its attachments rather to the place in which it resides than to the inhabitant. If the inhabitant quits the house the cat still remains; and if carried elsewhere seems for a while bewildered with its new situation. It must take time to become acquainted with the holes and retreats in which its prey resides, with all the little labyrinths through which they often make good an escape.

The cat is particularly fearful of water, of cold, and of ill smells. It loves to keep in the sun, to get near the fire, and to rub itself against those who carry perfumes. It is excessively fond of some plants, such as valerian, marum, and cat-mint: against these it rubs, smells them at a distance, and, at last, if they be planted in a garden, wears them out.

This animal eats slowly and with difficulty, as its teeth are rather made for tearing than chewing its aliments. For this reason it loves the most tender food, particularly fish, which it eats as well boiled as raw. Its sleeping is very light; and it often seems to sleep the better to deceive its prey. When the cat walks it treads very softly, and without the least noise; and as to the necessities of nature, it is cleanly to the last degree. Its fur, also, is usually sleek and glossy; and for this reason the hair is easily electrified, sending forth shining sparks if rubbed in the dark.

The wild cat breeds with the tame, and therefore the latter may be considered only as a variety of the former; however, they differ in some particulars. The cat in its savage state is somewhat larger than the house-cat—

and its fur, being longer, gives it a greater appearance than it really has; its head is bigger and its face flatter; the teeth and claws much more formidable; its muscles very strong, as being formed for rapine; the tail is of a moderate length, but very thick and flat, marked with alternate bars of black and white, the end always black; the hips and hind part of the lower joints of the leg are always black; the fur is very soft and fine: the general colour of these animals in England is a yellowish white mixed with a deep grey. These colours, though they appear at first sight confusedly blended together, yet, on close inspection, will be found to be disposed like the streaks on the skin of the tiger, pointing from the back downwards, rising from a black list that runs from the head along the middle of the back to the tail. This animal is found in our larger woods, and is the most destructive of the carnivorous kinds in this kingdom. It inhabits the most mountainous and woody parts of these islands, living mostly in trees, and feeding only by night. It often happens that the females of the tame kind go into the woods to seek mates among the wild ones. It seems that these, however, are not original inhabitants of this kingdom, but were introduced first in a domestic state, and afterwards became wild in the woods by ill usage or neglect. Certain it is, the cat was an animal much higher in esteem among our ancestors than it is at present. By the laws of Howel, the price of a kitten before it could see was to be a panny; till it caught a mouse, twopence; and when it commenced mouser, fourpence. It was required, besides, that it should be perfect in its senses of hearing and seeing, be a good mouser, have the claws whole, and be a good nurse. If it failed in any of these qualities, the seller was to forfeit to the buyer the third part of its value. If any one stole or killed the cat that guarded the prince's granary he was to forfeit a milch ewe, its fleece, and lamb; or as much wheat as, when poured on the cat suspended by the tail (the head touching the floor), would form a heap high enough to cover the tip of the former. From hence we discover, besides a picture of the simplicity of the times, a strong argument that cats are not naturally bred in our forests. An animal that could be so easily taken could never have been rated so highly; and the precautions laid down to improve the breed would have been superfluous in a creature that multiplies to such an amazing degree.

In our climate we know but of one variety of the wild cat; and, from the accounts of travellers, we learn that there are but few differences in this quadruped in all parts of the world. The greatest difference, indeed, between the wild cat and the tame one is rather to be found internally than in their outward form. Of all other quadrupeds the wild cat is, perhaps, that whose intestines are proportionably the smallest and the shortest. The intestines of the sheep, for instance, unravelled out and measured according to their length, will be found to be above thirty times the length of its body; whereas the wild cat's intestines, being measured out, will not be found above three times the length of its body. This is a surprising contrast; but we may account for it from the nature of the food in the two animals—the one living upon vegetables, which require a longer and a more tedious preparation before they can become a part of its body; the other living upon flesh, which requires very little alteration in order to be assimilated into the substance of the creature that feeds upon it. The one, therefore, wanted a long canal for properly digesting and straining its food; the other but a short one, as the food is already prepared to pass the usual secretions: however, a difficulty still remains behind—the intestines of the wild cat are one-third shorter than those of the tame one. How can we account for this? If we say that the domestic cat, living upon more plentiful and more nourishing provision, has its intestines

enlarged to the quantity with which it is supplied, we shall find this observation contradicted in the wild boar and the wolf, whose intestines are as long as those of the hog or the dog, though they lead a savage life, and, like the wild cat, are fed by precarious subsistence. The shortness, therefore, of the wild cat's intestines is still unaccounted for; and most naturalists consider the difficulty inextricable. We must leave it, therefore, as one of those difficulties which future observation or accident are most likely to discover.

This animal is one of those few which are common to the new continent as well as the old. When Christopher Columbus first discovered that country, a hunter brought him one which he had discovered in the woods, which was of the ordinary size, and the tail very long and thick. They were also common in Peru, although they were not rendered domestic. They are likewise well known in Africa and many parts of Asia. In some of these countries they are of a peculiar colour, and inclining to blue. In Persia, Pietro della Valle informs us that there is a kind of cat, particularly in the province of Chorasán, of the figure and form of the ordinary one, but infinitely more beautiful in the lustre and colour of its skin. It is of a grey blue, without mixture, and is soft and shining as silk. The tail is very long, and covered with hair six inches in length, which the animal throws upon its back like the squirrel. These cats are well known in France, and have been brought over to England under the name of the "blue cat," which, however, is not their colour.

Another variety of this animal is called by us the "lion cat," or, as others more properly term it, the "cat of Angora." These are larger than the common cat, and even than the wild one. Their hair is much longer, and hangs about their head and neck, giving this creature the appearance of a lion. Some of these are white, and others of a dun colour. These come from Syria and Persia—two countries which are noted for giving a long soft hair to the animals bred there. The sheep, the goats, the dogs, and the rabbits of Syria are all remarkable for the length and fine glossy softness of their hair; but particularly the cat, whose nature seems to be inflexible, conforms to the nature of the climate and soil, loses its savage colour, which it preserves in almost every other part of the world, and assumes the most beautiful appearance. There are some other varieties in this animal, but rather in colour than in form; and in general it may be remarked, that the cat when taken into other countries alters but very little, still preserving its natural manners, habits, and conformation.

**THE LION.**—The influence of climate upon mankind is but very small: he is found to subsist in all parts of the earth, as well under the frozen poles as beneath the torrid zone; but in animals the climate may be considered as congenial, and a kind of second nature. They almost all have their particular latitudes, beyond which they are unable to submit—either perishing with a moderate cold or dying for want of a frozen air, even in a temperate climate. The reindeer is never seen to depart from the icy fields of the north; and, on the contrary, the lion degenerates when taken from beneath the line. The whole earth is the native country of man; but all inferior animals have each their own peculiar districts.

Most terrestrial animals are found larger, fiercer, and stronger in the warm than in the cold or temperate climates. They are also more courageous and enterprising—all their dispositions seeming to partake of the ardour of their native soil. The lion produced under the burning sun of Africa is of all others the most terrible—the most undaunted. The wolf or the dog, instead of attempting to rival him, scarce deserves to attend his motions or become his providers. Such, however, of these animals as are bred in a more temperate climate,

or towards the tops of cold and lofty mountains, are far more gentle—or, to speak more properly, far less dangerous—than those bred in the torrid valleys beneath. The lions of Mount Atlas, the tops of which are covered with eternal snows, have neither the strength nor the ferocity of the lions of Bildulgerid or Zaara, where the plains are covered with burning sands. It is particularly in these frightful deserts that these enormous and terrible beasts are found that seem to be the scourge and terror of the neighbouring kingdoms. Happily, indeed, the species is not very numerous; and it seems to be diminishing daily; for those who have travelled through these countries assure us that there are by no means so many there at present as there were formerly; and Mr Shaw observes, that the Romans carried fifty times as many lions from Lybia in one year to combat in their amphitheatres as are to be found in the whole country at this time. The same remark is made with regard to Turkey, to Persia, and the Indies, where they are found to diminish in their numbers every day. Nor is it difficult to assign the cause of this diminution: it is obvious that it cannot be owing to the increase of the force of other quadrupeds, since they are all inferior to the lion, and, consequently, instead of lessening the number only tend to increase the supplies on which they subsist; it must therefore be occasioned by the increase of mankind, who is the only animal in Nature capable of making head against these tyrants of the forest and preventing their increase. The arms even of a Hottentot or a Negro make them more than a match for this powerful creature, and they seldom make the attack without coming off victorious. Their usual manner is to find out his retreat, and with spears headed with iron to provoke him to the combat; four men are considered as sufficient for this encounter; and he against whom the lion first receives him upon his spear, while the others attack him behind; the lion, finding himself wounded in the rear, turns that way, and then gives the man he first attacked an opportunity to recover. In this manner they attack him on all sides, until at last they entirely disable and then despatch him. This superiority is the numbers and the arts of man, that are sufficient to conquer the lion, serve also to enervate and discourage him; for he is brave only in proportion to the success of his former encounters. In the vast deserts of Zaara, in the burning sands that lie between Mauritania and Negroland, in the uninhabited countries that lie to the north of Caffaria, and, in general, in all the deserts of Africa where man has not fixed his habitation, the lions are found in great numbers, and preserve their natural courage and force. Accustomed to measure their strength with every animal they meet, the habit of conquering renders them intrepid and terrible. Having never experienced the dangerous arts and combinations of man, they have no apprehensions from his power. They boldly face him, and seem to brave the force of his arms. Wounds rather serve to provoke their rage than to repress their ardour. They are not daunted even with the opposition of numbers; a single lion of the desert often attacks an entire caravan; and, after an obstinate combat, when he finds himself overpowered, instead of flying, he continues to combat, retreating, and still facing the enemy till he dies. On the contrary, the lions which inhabit the peopled countries of Morocco or India, having become acquainted with human power and experienced man's superiority, have lost all their courage, so as to be scared away with a shout, and seldom attack any but the unresisting flocks or herds, which even women and children are sufficient to protect.

This alteration in the lion's disposition sufficiently shows that he might easily be tamed, and admit of a certain degree of education. In fact, nothing is more common than for keepers of wild beasts to play with this animal, to pull out his tongue, and even to chastise him without a cause. He seems to bear it all with the utmost

composure; and we very rarely have instances of his revenging these unprovoked sallies of impertinent cruelty. However, when his anger is at last excited the consequences are terrible. Labat tells us of a gentleman who kept a lion in his chamber, and employed a servant to attend it, who, as is usual, mixed his blows with caresses. This ill-judged association continued for some time; till one morning the gentleman was awakened by a noise in his room, which at first he could not tell the cause of; but, drawing the curtains, he perceived a horrid spectacle—the lion growling over the man's head, which he had separated from the body, and tossing it round the floor. He immediately, therefore, flew into the next room, called to the people without, and had the animal secured from doing further mischief. However, this single account is not sufficient to weigh against the many instances we every day see of this creature's gentleness and submission. He is often bred up with other domestic animals, and is seen to play innocently and familiarly among them; and if it ever happens that his natural ferocity returns, it is seldom exerted against his benefactors. As his passions are strong and his appetites vehement, one ought not to presume that the impressions of education will always prevail: so that it would be dangerous in such circumstances to suffer him to remain too long without food, or to persist in irritating and abusing him: however, numbers of accounts assure us that his anger is noble, his courage magnanimous, and his disposition grateful. He has been often seen to despise contemptible enemies, and pardon their insults when it was in his power to punish them. He has been seen to spare the lives of such as were thrown to be devoured by him, to live peaceably with them, to afford them a part of his subsistence, and sometimes to want food himself rather than deprive them of that life which his generosity had spared.

It may also be said that the lion is not cruel, since he is so only from necessity, and never kills more than he consumes. When satiated, he is perfectly gentle; while the tiger, the wolf, and all the inferior kinds, such as the fox, the pole-cat, and the ferret, kill without remorse, are fierce without cause, and by their indiscriminate slaughter, seem rather to satisfy their malignity than their hunger.

The outward form of the lion seems to speak his internal generosity. His figure is striking, his look confident and bold, his gait proud, and his voice terrible. His stature is not overgrown like that of the elephant or rhinoceros; nor is his shape clumsy, like that of the hippopotamus or the ox. It is compact, well proportioned, and sizeable—a perfect model of strength joined with agility. It is muscular and bold, neither charged with fat nor unnecessary flesh. It is sufficient but to see him in order to be assured of his superior force. His large head surrounded with a dreadful mane—all those muscles that appear under the skin swelling with the slightest exertions—and the great breadth of his paws, with the thickness of his limbs, plainly evince that no other animal in the forest is capable of opposing him. He has a very broad face, that, as some have imagined, resembles the human. It is surrounded with very long hair, which gives it a very majestic air. The top of the head, the temples, the cheeks, the under jaw, the neck, the breast, the shoulder, the hinder part of the legs, and the belly, are furnished with it, while all the rest of the body is covered with very short hair, of a tawny colour. The length of the hair in many parts, and the shortness of it in others, serves a good deal to disguise this animal's real figure. The breast, for instance, appears very broad, but in reality it is as narrow and contracted in proportion as that of the generality of dogs and horses. For the same reason the tail seems to be of an equal thickness from one end to the other, on account of the inequality of the hair with which it is encompassed—it being shorter near the insertion where

the flesh and bones are large, and growing longer in proportion as its real thickness lessens towards the point, where it ends in a tuft. The hair about the neck and breast is not different from that on the rest of the body, except in its length; nor is each hair pointed as in most other animals, but of an equal thickness from one end to the other. The neck is very strong, but not composed of one solid bone, as Aristotle has imagined; on the contrary, though very short and muscular, it has as many bones as the camel or the horse; for it is universal to all quadrupeds to have seven joints in the neck, and not one of them have either more or less. However, the muscles in the neck of the lion that tie the bones together are extremely strong, and have somewhat the appearance of bones; so that ancient authors who have treated of this animal have mistaken the whole for a single bone. The tongue is rough, and beset with prickles as hard as a cat's claws; these have the grain turned backwards; so that it is probable a lion, if it should attempt to lick a man's hand, as we are told it sometimes does, would tear off the skin. The eyes are always bright and fiery; nor even in death does this terrible look forsake them. In short, the structure of the paws, teeth, eyes, and tongue are the same as in a cat; and also in the inward parts these two animals so nearly resemble each other, that the anatomists's chief distinction arises merely from the size.

The lion has, as was observed before, a large mane, which grows every year longer as the animal grows older; the lioness is without this ornament at every age. This mane is not coarse or rough as in a horse, but composed of the same hair with the rest of the body, lengthened and shining. The mane as well as the rest of the body is of a yellow colour; nor is there ever any difference to be found in the colour of one lion from that of another. What the ancients might have said concerning black lions, or white, or streaked like the tiger, is not confirmed by modern experience; so that these varieties have never been seen, or exist no longer.

It is usually supposed that the lion is not possessed of the sense of smelling in such perfection as most other animals. It is also observed that too strong a light greatly incommodes him. This is more than probable from the formation of his eyes, which, like those of the cat, seem fitted for seeing best in the dark. For this reason he seldom appears in open day, but ravages chiefly by night; and not only the lion, but all other animals of the cat kind, are kept off by the fires which the inhabitants light to preserve their herds and flocks; the brightness of the same dazzles their eyes, which are only fitted for seeing in the dark; and they are afraid to venture blindly into those places which they know to be filled with their enemies. It is equally true of all this kind that they hunt rather by the sight than the smell; and it sometimes happens that the lion pursues either the jackall or the wild dog while they are hunting upon the scent; and when they have run the beast down he comes in and monopolises the spoil. From hence, probably, may have arisen the story of the lion's provider: these little industrious animals may often, it is true, provide a feast for the lion; but they have hunted merely for themselves, and he is an unwelcome intruder upon the fruits of their toil.

The lion, when hungry, boldly attacks all animals that come in his way; but as he is very formidable, and as they all seek to avoid him, he is often obliged to hide in order to take them by surprise. For this purpose he crouches on his belly in some thicket or among the long grass, which is found in many parts of the forest; in this retreat he continues, with patient expectation, until his prey comes within a proper distance, and he then springs after it, fifteen or twenty feet from him, and often seizes it at the first bound. If he misses the effort, and in two or three reiterated springs cannot seize his prey, he continues motionless for a time, seems to be very sensible

of his disappointment, and waits for a more successful opportunity. In the deserts and forests his most usual prey are the gazelles and the monkeys, with which the torrid regions abound. The latter he takes when they happen to be upon the ground, for he cannot climb trees like the cat or the tiger. He devours a great deal at a time, and generally fills himself for two or three days to come. His teeth are so strong that he very easily breaks the bones, and swallows them with the rest of the body. It is reported that he sustains hunger a very long time, but thirst he cannot support in an equal degree, his temperament being extremely hot; some have even asserted that he is in a continual fever. He drinks as often as he meets with water, lapping it like a cat, which, as we know, drinks but slowly. He generally requires about fifteen pounds of raw flesh in a day; he prefers that of live animals, and particularly those which he has just killed. He seldom devours the bodies of animals when they begin to putrefy; and he chooses rather to hunt for a fresh spoil than to return to that which he had half devoured before. However, though he usually feeds upon fresh provision, his breath is very offensive and his urine insupportable.

The roaring of the lion is so loud, that when it is heard in the night and re-echoed by the mountains it resembles distant thunder. This roar is his natural note, for when enraged he has a different growl, which is short, broken, and reiterated. The roar is a deep hollow growl, which he sends forth five or six times a day, particularly before rain. The cry of anger is much louder and more formidable. This is always excited by opposition; and upon those occasions, when the lion summons up all his terrors for the combat, nothing can be more terrible. He then lashes his sides with his long tale, which alone is strong enough to lay a man level; he moves his mane in every direction—it seems to rise and stand like bristles round his head; the skin and muscles of his face are all in agitation; his huge eye-brows half cover his glaring eye-balls; he discovers his teeth, which are formed rather for destruction than chewing his food; he shows his tongue covered with points, and extends his claws, which appear almost as long as a man's fingers. Prepared in this manner for war, there are few animals that will venture to engage him; and even the boldest of the human kind are daunted at his approach. The elephant, the rhinoceros, the tiger, and the hippopotamus, are the only animals that are not afraid singly to make opposition.

Nevertheless, neither the leopard nor the wild boar if provoked will shun the combat; they do not seek the lion to attack, but will not fly at his approach; they wait his onset, which he seldom makes unless compelled by hunger; they then exert all their strength, and are sometimes successful. We are told of a combat between a lion and a wild boar, in a meadow near Algiers, which continued for a long time with incredible obstinacy: at length, both were seen to fall from the wounds they had given each other, and the ground all about them was covered with their blood. These instances, however, are very rare, for the lion is in general the undisputed master of the forest. Man is the only creature that attacks him with almost certain success, with the assistance of dogs and horses, which are trained to the pursuit. These animals—which, in a state of nature, would have fled from the presence of the lion in an agony of consternation—when conscious of the assistance of man, become pursuers in their turn, and boldly hunt their natural tyrant. The dogs are always of the large breed; and the horses, as Gesner assures us, must be of that sort called "charossi," or lion-eyed—all others of this kind flying at the sight of the lion, and endeavour to throw their riders. When the lion is roused he recoils with a slow, stately motion; he never goes off directly forward, nor measures his paces equally, but takes an oblique course, going from one side to the other, and bounding rather than running. When the hunters

approach him they either shoot or throw their javelins, and in this manner disable him before he is attacked by the dogs, many of whom he would otherwise destroy. He is very vivacious, and is never killed at once, but continues to fight desperately even after he has received his mortal blow. He is also taken by pit-falls—the natives digging a deep hole in the ground, and covering it slightly over with sticks and earth, which, however, give way beneath his weight, and he sinks to the bottom, from whence he has no means of escape. But the most usual manner of taking this animal is while yet a cub, and incapable of resistance. The place near the den of the lioness is generally well known by the extent of her depredations on that occasion; the natives, therefore, watch the time of her absence, and, aided by a swift horse, carry off her cubs, which they sell to strangers, or to the great men of their country.

The lion, while young and active, lives by hunting in the forest at a great distance from any human habitation, and seldom quits this retreat while able to subsist by his natural industry; but when he becomes old and unfit for the purposes of surprise, he boldly comes down into places more frequented, attacks the flocks and herds that take shelter near the habitation of the shepherd or the husbandman, and depends rather upon his courage than his address for support. It is remarkable, however, that when he makes one of these desperate sallies, if he finds men and quadrupeds in the same field he only attacks the latter, and never meddles with men unless they provoke him to engage. It is said that he prefers the flesh of camels to any other food; he is likewise said to be fond of that of young elephants; these he often attacks before their trunk is yet grown; and unless the old elephant comes to their assistance he makes them an easy prey.

The lion is terrible upon all occasions, but particularly at those seasons when he is incited by desire, or when the female has brought forth. It is then that the lioness is seen followed by eight or ten males, who fight most bloody battles among each other, till one of them becomes victorious over all the rest. She is said to bring forth in spring, and to produce but once a year. With respect to the time of gestation naturalists have been divided, some affirming that the lioness went with young six months, and others but two. The time, also, of their growth and their age have hitherto been lost in obscurity—some asserting that they acquired their full growth in three years, and others that they required a longer period to come to perfection; some saying (and among this number is Mr. Buffon) that they lived to but twenty years, or twenty-two at most; others making their lives even of shorter duration. All these doubts are now reduced to certainty—for we have had several of these animals bred in the Tower; so that the manner of their copulation, the time of their gestation, the number they bring forth, and the time they take to come to perfection, are all pretty well known. Although the lion emits his urine backwards, yet he couples in the ordinary manner; and, as was said before, his internal structure in almost every respect resembles that of a cat. The lioness, however, is upon these occasions particularly fierce, and often wounds the lion in a terrible manner. She goes with young, as I am assured by her keeper, no more than five months; the young ones, which are never more than two in number when brought forth, are about the size of a large pug dog—harmless, pretty, and playful; they continue the teat for twelve months, and the animal is more than five years in coming to perfection. As to its age, from its imprisoned state we can have no certainty; since it is very probable that, being deprived of its natural climate, food, and exercise, its life must be very much abridged. However, naturalists have hitherto been greatly mistaken as to the length of its existence. The great he-lion, called "Pompey," which died in the year 1760, was known to

have been in the Tower for above seventy years; and one lately died there, which was brought from the river Gambia, that died above sixty-three. The lion, therefore, is a very long-lived animal; and, very probably, in his native forests his age exceeds even that of man himself.

In this animal all the passions, even of the most gentle kind, are in excess, but particularly the attachment of the female to her young. The lioness, though naturally less strong, less courageous, and less mischievous than the lion, becomes terrible when she has got young ones to provide for. She then makes her incursions with even more intrepidity than the lion himself; she throws herself indiscriminately among men and other animals—destroys without distinction—loads herself with the spoil, and brings it home reeking to her cubs, whom she accustoms betimes to cruelty and slaughter. She usually brings forth in the most retired and inaccessible places; and, when she fears to have her retreat discovered, often hides her tracks by retracing her ground, or by brushing them out with her tail. She sometimes, also, when her apprehensions are great, transports them from one place to another, and, if obstructed, defends them with determined courage, and fights to the last.

The lion is chiefly an inhabitant of the torrid zone, and, as was said, is always most formidable there; and yet he can subsist in more temperate climates: there was a time when even the southern parts of Europe were infested by him. At present he is only found in Africa and the East Indies, in some of which countries he grows to an enormous height. The lion of Bildulgerid is said to be nearly five feet high, and between nine and ten feet from the tip of the nose to the insertion of the tail. We have in the Tower at present one above four feet high, which was brought from Morocco, and which is the largest that for some time past has been seen in Europe. The ordinary size is between three and four feet—the female being in all her dimensions about one-third less than the male. There are no lions in America: the puma, which has received the name of the "American lion," is comparatively a very contemptible animal, having neither the shape, the size, nor the mane of the lion—being known to be extremely cowardly, to climb trees for its prey, to subsist rather by its cunning than its courage, and to be inferior even to the animal that goes by the name of the "American tiger." We ought not, therefore, to confound this little treacherous creature with the lion, which all the ancients have concurred in denominating the "king of beasts," and which they have described as brave and merciful. Indeed, the numerous accounts which they have given us of this animal's generosity and tenderness show that there must be some foundation for the general belief of its good qualities; for mankind seldom err when they are all found to unite in the same story. However, perhaps the caution of Aristophanes, the comic poet, is better followed in practice, who advises us to have nothing to do with this creature, but to let the lioness suckle her own whelps.

**THE TIGER.**—The ancients had a saying, "That as the peacock is the most beautiful among birds, so is the tiger among quadrupeds." In fact, no quadruped can be more beautiful than this; the glossy smoothness of its hair—which lies much smoother and shines with greater brightness than even that of the leopard—the extreme blackness of the streaks with which he is marked, and the bright yellow colour of the ground which they diversify, at once strike the beholder. To this beauty of colouring is added an extremely elegant form, much larger, indeed, than that of the leopard, but more slender, more delicate, and bespeaking the most extreme swiftness and agility. Unhappily, however, this animal's disposition is as mischievous as its form is admirable, as if Providence was willing to show the small value

of beauty by bestowing it on the most noxious of quadrupeds. We have at present one of these animals in the Tower, which to the view appears the most good-natured and harmless creature in the world; its physiognomy is far from fierce or angry; it has not the commanding, stern countenance of the lion, but a gentle, placid air; yet for all this it is fierce and savage beyond measure; neither correction can terrify it nor indulgence can tame.

The chief and most observable distinction in the tiger, and in which it differs from all others of the mottled kind, is in the shape of its colours, which run in streaks or bands in the same direction as his ribs, from the back down to the belly. The leopard, the panther, and the ounce are all partly covered like this animal, but with this difference—their colours are broken in spots all over the body, whereas in the tiger they stretch lengthwise, and there is scarce a round spot to be found on his skin. Besides, there are other observable distinctions: the tiger is much larger, and often found bigger than even the lion himself; it is also much more slender in proportion to its size—its legs shorter, and its neck and body longer. In short, of all other animals it most resembles the cat in shape; and, if we conceive the latter magnified to a very great degree, we shall have a tolerable idea of the former.

In classing carnivorous animals we may place the lion foremost; and immediately after him follows the tiger which seems to partake of all the noxious qualities of the lion without sharing any of his good ones. To pride, courage, and strength the lion joins greatness, clemency, and generosity: but the tiger is fierce without provocation, and cruel without necessity. The lion seldom ravages except when excited by hunger; the tiger, on the contrary, though glutted with slaughter, is not satisfied, still continues the carnage, and seems to have its courage only inflamed by not finding resistance. In falling in among a flock or a herd it gives no quarter, but levels all with indiscriminate cruelty, and scarce finds time to appease its appetite while intent upon satisfying the malignity of its nature. It thus becomes the scourge of the country where it is found; it fears neither the threats nor the opposition of mankind; the beasts, both wild and tame, fall equally a sacrifice to its insatiable fury; the young elephant and the rhinoceros become equally its prey; and it not unfrequently ventures to attack even the lion himself.

Happily for the rest of Nature, this animal is not very common, and the species is chiefly confined to the warmest provinces of the East. The tiger is found in Malabar, in Siam, in Bengal, and in all the countries which are inhabited by the elephant or the rhinoceros. Some even pretend that it has a friendship for and often accompanies the latter in order to devour its excrements, which serve it as a purge. Be this as it will, there is no doubt but that they are often seen together at the sides of lakes and rivers, where they are probably both compelled to go by the thirst which in that torrid climate they must very often endure. It is likely enough, also, that they seldom make war upon each other—the rhinoceros being a peaceable animal, and the tiger knowing its strength too well to venture the engagement. It is still more likely that the tiger finds this a very convenient situation, since it can there surprise a greater number of animals which are compelled thither from the same motives. In fact, it is generally known to lurk near such places where it has an opportunity of choosing its prey, or rather of multiplying its massacres. When it has killed one it often goes to destroy others, swallowing their blood down at large draughts, and seeming rather glutted than satiated with its abundance.

However, when it has killed a large animal, such as a horse or a buffalo, it immediately begins to devour it on the spot, fearing to be disturbed. In order to feast at his ease, he carries off his prey to the forest, dragging it

along with such ease, that the swiftness of its motion seems scarce retarded by the enormous load it sustains. From this alone we may judge of its strength; but to have a more just idea of this particular, let us stop a moment to consider the dimensions of this most formidable creature. Some travellers have compared it for size to a horse, and others to a buffalo, while others have contented themselves with saying that it is much larger than a lion. We have recent accounts of this animal's magnitude that deserve the utmost confidence. Mr. Buffon has been assured by one of his friends that he saw a tiger in the East Indies of fifteen feet long. Supposing he means including the tail, this animal, allowing four feet for that, must have been eleven feet from the tip of the nose to the insertion of the tail. Indeed, that which is now in the Tower is not so large, being, as well as I could measure, six feet from the tip to the insertion, and the tail was three feet more. Like all the rest of its kind its motions are irregular and desultory; it bounds rather than runs; and, like them, rather chooses to take its prey by surprise than to be at the trouble of hunting it down. How large a leap it can take at once we may easily judge, by comparing what it might do to what we see so small an animal as the cat actually perform. The cat can leap several feet at a bound; and the tiger, who is ten times as long, can no doubt spring proportionably.

The tiger is the only animal whose spirit seems untameable. Neither force nor constraint, neither violence nor flattery, can prevail in the least on its stubborn nature. The caresses of the keeper have no influence on their heart of iron; and time, instead of mollifying its disposition, only serves to increase its fierceness and malignity. The tiger snaps at the hand that feeds it as well as that by which it is chastised; every object seems considered only as its proper prey, which it mentally devours with a look; and, although confined by bars and chains, still makes fruitless efforts, as if to show its malignity when incapable of exerting its force.

To give a still more complete idea of the strength of this terrible creature we shall quote a passage from Tæcbar, who was an eye-witness of a combat between a tiger and three elephants at Siam. For this purpose, the king ordered a lofty pallisade to be built of bamboo cane, about a hundred feet square; and in the midst of this were three elephants appointed for combating the tiger. Their heads and a part of their trunk were covered with a kind of armour, like a mask, which defended that part from the assaults of the fierce animal with which they were to engage. As soon, says this writer, as we arrived at the place a tiger was brought forth from its den, of a size much larger than we had ever seen before. It was not at first let loose, but held with cords, so that one of the elephants approaching gave it three or four terrible blows with its trunk on the back, with such force that the tiger was for some time stunned, and lay without motion as if it had been dead. However, as soon as it was let loose and at full liberty, although the first blows had greatly abated its fury, it made at the elephant with a loud shriek, and aimed at seizing his trunk; but the elephant, wrinkling it up with great dexterity, received the tiger on his great teeth and tossed it up into the air. This so discouraged the furious animal that it no more ventured to approach the elephant, but made several circuits round the pallisade, frequently attempting to fly at the spectators. Shortly afterwards three elephants were sent against it, and they continued to strike it with such terrible force with their trunks that it once more lay for dead; and they certainly would have killed it had not there been a stop put to the combat.

From this account we may readily judge of the great strength and courage of this animal, which, though reduced to captivity and held by cords—though first disabled and set alone against three, yet ventured to

continue the engagement—and even that against animals covered and protected from its fury.

Captain Hamilton informs us that in the Sunda Rajah's dominions there are three sorts of tigers in the woods, and that the smallest are the fiercest. This is not above two feet high, appears to be extremely cunning, and delights in human flesh. The second kind is about three feet high, and hunts deer and wild hogs, besides the little animal which has been already described under the name of the "chevrotain," or "Guinea deer." The tiger of the largest sort is above three feet and a half high; but, although endowed with greater powers, it is by no means so rapacious as either of the former. This formidable animal, which is called the "royal tiger" (one of which we have at present in the Tower), does not appear to be so ravenous nor so dangerous, and is even more cowardly. A peasant in that country, as the same traveller informs us, had a buffalo which fell into a quagmire, and while he went for assistance there came a large tiger, and with its single strength drew forth the animal, which the united force of many men could not effect. When the people returned to the place the first object they beheld was the tiger, who had thrown the buffalo over its shoulder as a fox does a goose, and was carrying it away with the feet uppermost towards its den; however, as soon as it saw the men it relinquished its prey, and instantly fled to the woods; but it had previously killed the buffalo and sucked its blood—and no doubt the people were perfectly well satisfied with its retreat. It may be observed that some East Indian buffaloes weigh above a thousand pounds, which is twice as heavy as the ordinary run of black cattle; so that from hence we may form a conception of the enormous strength of this rapacious animal, that could thus run off with a weight at least twice as great as that of itself.

Were this animal as common as the panther, or even the lion himself, thus furnished as it is with the power to destroy and the appetite for slaughter, the country would be uninhabitable where it resides. But luckily the species is extremely scarce, and has been so since the earliest accounts we have had of the tiger. About the time of Augustus, we are assured by Pliny that when panthers were brought to Rome by hundreds a single tiger was considered as an extraordinary sight; and he says that the Emperor Claudius was able to obtain four only, which shows with what difficulty they were procured. The incredible fierceness of this animal may in some measure be the cause of the scarcity which was then felt in Rome, since it was the opinion of Varo that the tiger was never taken alive; but its being a native only of the East Indies, and that particularly of the warmer regions, it is not to be wondered that the species should be so few.

We may therefore consider the species of the true streaked tiger as one of the scarcest of animals, and much less diffused than that of the lion. As to the number of its young we have no certain accounts; however, it is said that it brings forth four or five at a time. Although furious at all times, the female on such occasions exceeds her usual rapacity; and, if her young are taken from her, she pursues the spoiler with incredible rage. To save a part he drops one of her cubs, which she picks up and again returns to her den, when again she pursues him; he then drops another—and by the time she has returned with that he generally escapes with the remainder. If she loses her young entirely she then becomes desperate—boldly approaches even the towns themselves, and commits terrible slaughter. The tiger expresses its resentment in the same manner as the lion; it moves the muscles and skin of its face, shows its teeth, and shrieks in the most frightful manner. Its note is very different from that of the lion—being rather a scream than a roar.

The skin of these animals is much esteemed in all

parts of the East, particularly in China; the Mandarins cover their seats of justice in the public places with it, and convert it into coverings for cushions in winter. In Europe, these skins, though but seldom to be met with, are of no great value, those of the panther and the leopard being held in much greater estimation. This is all the little benefit we derive from this dreadful animal, of which so many falsehoods have been reported—as, that its sweat was poisonous, and the hair of its whiskers more dangerous than an envenomed arrow. But the real mischiefs which the tiger occasions while living are sufficient, without giving imaginary ones to the parts of its body when dead. In fact, the Indians sometimes eat its flesh, and find it neither disagreeable nor unwholesome.

There is an animal of America which is usually called the "red tiger," but Mr. Buffon calls it the "cougar," which no doubt is very different from the tiger of the East. Some, however, have thought proper to rank both together; and I will take leave to follow their example, merely because the cougar is more like the tiger in everything, except the colour, than any other animal I know—having the head, the body, and the neck shaped very much in the same manner. Of these slight differences words would give but a very faint idea; it will therefore be sufficient to observe that they are both equally slender, and are smaller where the neck joins the head than others of the panther kind. There is one at present in the Tower; and it seemed to me, as well as I could see it through the bars, that were it properly streaked and coloured it would in all things resemble a small tiger. It is, however, of a very different colour, being of a deep brown, and the tail very long and pointed. It is rather darker on the back; under the chin it is a little whitish, as also on the lower part of the belly.

Of all the American animals this is the most formidable and mischievous, even their pretended lion not excepted. It is said there are several sorts of them; and, as well as I can remember, I have seen one or two here in England differing from the present both in size and conformation. It is indeed a vain endeavour to attempt to describe all the less obvious varieties in the cat kind. If we examine them minutely we shall find the differences multiply upon us so much, that instead of a history we shall only be paid with a catalogue of distinctions. From such of them as I have seen within the last six years, I think I could add two animals of this species that have not been hitherto described, and with the names of which he that showed them was utterly unacquainted. But it is a poor ambition—that of being eager to find out new distinctions, or adding one noxious animal more to a list already sufficiently numerous. Were the knowing a new variety to open an unknown history, or in the least to extend our knowledge, the inquiry would then be worth pursuing; but what signifies mentioning some trifling difference, and from thence becoming authors of a new name, when the difference might have originally proceeded either from climate, soil, or indiscriminate copulation?

The cougars are extremely common in South America; and, where the towns border upon the forest, they make frequent incursions by night into the midst of the streets, carrying off fowls, dogs, and other domestic creatures. They are, however, but weak and contemptible compared to the great tiger, being found unable to cope with a single man. The Negroes and Indians are very dexterous in encountering them; and some, even for the sake of their skins, seek them in their retreats. The arms in this combat, seemingly so dangerous, are only a lance of two or three yards long, made of heavy wood, with the point hardened in the fire; and a kind of scymitar of about three quarters of a yard in length. Thus armed they wait till the tiger makes an assault against the left hand, which holds the lance, and is wrapped up

in a short cloak of baize. Sometimes the animal, aware of the danger, seems to decline the combat; but then its antagonist provokes it with a slight touch of the lance, in order, while he is defending himself, to strike a sure blow. As soon, therefore, as the creature feels the lance, it grasps it with one of its paws, and with the other strikes at the arm which holds it. Then it is that the person nimbly aims a blow with his scymitar, which he kept concealed, with the other hand, and hamstringing the creature, which immediately draws back enraged, but instantly returns to the charge. But then, receiving another stroke, it is totally deprived of the power of motion: and the combatant, killing it at his leisure, stripes the skin, cuts off the head, and returns to his companions, displaying these as the trophies of his victory.

This animal, as we are assured, is often more successful against the crocodile; and it is the only quadruped in that part of the world that is not afraid of the engagement. It must be no unpleasant sight to observe from a place of safety this extraordinary combat between animals so terrible and obnoxious to man. Such as have seen it describe it in the following manner:—When the tiger, impelled by thirst that seems continually to consume it, comes down to the river-side to drink, the crocodile, which makes no distinction in its prey, lifts its head above water to seize it; the tiger, not less rapacious than the other; and unacquainted with the force of the enemy, boldly ventures to seize it, and plunges its claws into the eyes of the crocodile, which is the only vulnerable part of its body: upon this the crocodile instantly dives under water, and the tiger goes down with him—for it will sooner die than let go its hold. In this manner the combat continues for some time, until the tiger is drowned, or escapes, as is sometimes the case, from its disabled enemy.

These animals are common in Guiana. They were formerly seen swimming over in great numbers into the island of Cayenne, to attack and ravage the flocks and herds of the inhabitants. In the beginning they were a terrible scourge to the infant colony; but by degrees they were repulsed and destroyed, and are now seen no longer at that place. They are found in Brazil, in Paraguay, in the country of the Amazons, and in several other parts of South America. They often climb trees in quest of prey, or to avoid their pursuers. They are deterred by fire, like all other animals of the cat kind: or, more properly speaking, they seldom venture near those places where they see it kindled, as they are always sure of their enemies being near, and their nocturnal eyes are dazzled by the brightness of the blaze. From the description of this animal, one would be hardly led to suppose that its flesh was good for food; and yet we have several accounts which allege the fact, some asserting it to be superior even to mutton: however, what Monsieur Des Marchais observes is most likely to be true—namely, that the most valuable part of this animal is its skin, and that its flesh is but indifferent eating, being generally lean, and usually having a strong taste.

THE PANTHER AND THE LEOPARD.—We have hitherto found no great difficulty in distinguishing one animal from another, each carrying its own peculiar marks, which in some measure serve to separate it from all the rest. But it is otherwise when we come to those of the cat kind which fill up the chasm between the tiger and the cat. The spots with which their skins are diversified are so various and their size so equivocal, that it is no easy matter to distinguish the species, particularly as we have little else but the spots and the size to guide us in making the distinction. If we regard the figure and diversity of the spots, we shall find many varieties not taken notice of by any naturalists; if we are led by the size, we shall find an imperceptible gradation from the cat to the tiger. It would be vain, therefore, to make as many varieties in these animals as we see differences in

spots or stature; it will be sufficient to seize the most general distinctions, and leave the rest to such as are fond of more minute disquisitions.

Of all this tribe, whose skins are so beautifully spotted and whose natures are so mischievous, the panther may be considered as the foremost. This animal has been by many naturalists mistaken for the tiger; and, in fact, it approaches next to it in size, fierceness, and beauty. It is distinguished, however, by one obvious and leading character—that of being spotted, not streaked; for in this particular the tiger differs from the panther, the leopard, and almost all the inferior ranks of this mischievous family.

This animal, which Mr. Buffon calls simply the “panther,” Linnaeus the “pard,” Geener the “pardalis,” and the modern Latins the “leopardus”—this animal, I say, which goes by too many names, and which the English have indiscriminately called by the name of the “panther” or the “leopard,” may be considered as the largest of the kind, and is spotted in a manner somewhat different from those that are smaller. As these spots, however, make the principal difference between it and the lesser animals, which it otherwise resembles in shape, size, disposition, and beauty, I will first show these slight distinctions, and mention the names each animal has received in consequence thereof; and then proceed to give their history together, still marking any peculiarity observable in one of the species which is not found in the rest.

Next to the great panther, already mentioned, is the animal which Mr. Buffon calls the “leopard”—a name which he acknowledges to be given arbitrarily for the sake of distinction. Other naturalists have not much attended to the slight differences between this and the great panther, or have they considered its discriminations as sufficient to entitle it to another name. It has hitherto, therefore, gone under the name of the “leopard,” or “panther of Senegal,” where it is chiefly found. The differences between this animal and the former are these—the large panther is often found to be six feet long from the tip of the nose to the insertion of the tail; the panther of Senegal is not above four. The large panther is marked with spots in the manner of a rose—that is, five or six make a kind of circle, and there is generally a large one in the middle; the leopard of Senegal has a much more beautiful coat—the yellow is more brilliant and the spots are smaller, and not disposed in rings, but in clusters. As to the rest, they are both whitish under the belly; the tail in both is pretty long, but rather longer in proportion in the latter than the former. To these two animals, whose differences seem to be so very minute, we may add a third—namely the “jaguar,” or “panther of America.” This in every respect resembles the two former, except in the disposition of its spots, and that its neck and head are rather streaked than spotted. The jaguar is also said to be lower upon its legs, and less than the leopard of Senegal. These three quadrupeds, as we see, have but very slight differences, and the principal distinction used by Mr. Buffon is taken from the size; the first, as he says, is usually six feet long, the second four feet, and the last about three; however, it appears from the particular subjects of his description that the panther in his possession was not above three feet seven inches long; that the leopard’s skin which he describes was about four; and the jaguar at two years old was between two and three feet long, which, when come to its full growth, would no doubt be four feet long as well as the two former. From hence, therefore, we may conclude that the size in these animals is not sufficient to make a distinction among them; and that those who called them all three by the indiscriminate names of the leopard and the panther, if not right, were at least excusable. Of these which are now to be seen in the Tower, the jaguar or the American panther is rather the largest of

the three, and is by no means the contemptible animal which Mr. Buffon describes it to be; the leopard is the least of them, and has by some travellers been supposed to be an animal produced between the panther and the ounce—an animal which resembles but is less than any of the former. These three animals we may therefore rank together, as they agree pretty nearly in their robe, their size, their dispositions, and their ferocity.

We come next to an animal confessedly different from any of the former, being much smaller, and its colour more inclining to white. Its name, however, in our language has caused no small confusion. It has been generally called by foreigners the “onza” or “ounce,” and this name some of our own writers have thought proper to give it; but others of them, and these the most celebrated, such as Willoughby, have given the name to a different animal, with a short tail, and known to the ancients and moderns by the name of the “lynx.” I confess myself at a loss in this case whom to follow; the alteration of names should be always made with great caution, and never but in cases of necessity. If we follow Willoughby, there will be an animal of the panther kind very distinguishable from all the rest left without a name; and if we recede from him, it will serve to produce some confusion among all the numerous class of readers and writers who have taken him for their guide: however, as he seems himself to have been an innovator, the name of the lynx having been long adopted into our language before, it was unnecessary to give the animal that bore it another name, and to call that creature an ounce which our old writers had been accustomed to know by the Latin appellation; for this reason, therefore, we may safely venture to take a name, which has long been misapplied, from the lynx, and restore it to the animal in question. We will therefore call that animal of the panther kind which is less than the panther, and with a longer tail, the “ounce;” and the lynx may remain in possession of that name by which it was known among our old English writers as well as by all antiquity.

The “ounce,” or the “onza” of Linnaeus, is much less than the panther, being no more at most than three feet and a half long: however, its hair is much longer than that of the panther, and its tail more so. The panther of four or five feet long has a tail but of two feet, or two feet and a half. The ounce, which is about three feet, has a tail often longer than the rest of its body. The colour of the ounce is also apparently different, being rather more inclining to a cream-colour, which is deeper on the back and whiter towards the belly. The hair on the back is an inch and a half long, and that on the belly two inches and a half, which is much longer than that of the panther. Its spots are disposed pretty much in the same manner as the large panther, except that on the haunches it is rather marked with stripes than with spots.

Descending to animals of this kind that are still smaller, we find the “catamountain,” which is the ocelot of Mr. Buffon, or the tiger-cat of most of those who exhibit as a show. It is less than the ounce, but its robe more beautifully variegated. It is an American animal, and is about two feet and a half in length from the nose to the insertion of the tail. It is extremely like a cat, except that it is larger and slenderer—that its colours are more beautiful and its tail rather shorter. The fur is of a redish colour, the whole beautified with black spots and streaks of different figures. They are long on the back, and round on the belly and paws. On the ears are black stripes, which run across; but in other respects they entirely resemble those of a cat. These colours, however, which naturalists have taken great pains minutely to describe, are by no means permanent, being differently disposed in different animals of the same species. I remember to have seen an animal of this size—but whether of this species I will not pretend to say—some years ago

that was all brown, and was said to come from America.

From this tribe of the cat kind, with spotted skins and a long tail, we come to another with skins diversified in like manner, but with a shorter tail. The principal amongst these is the "lynx"—the name by which the animal was known to Ælian among the ancients, and to all our old English writers among those of a more modern date. This name has been corrupted by the Portuguese into the word "ouze;" and this corruption has been adopted by Ray, who has improperly called this animal the "ounce," after some of the foreign travellers. The first striking distinction between the lynx and all those of the panther kind is in its tail, which is at least half as short in proportion, and black at the extremity. Its fur is much longer, the spots on the skin less vivid, and but confusedly mingled with the rest. Its ears are much longer, and tipped at the point with a black tuft of hair. The colour round the eyes is white, and the physiognomy more placid and gentle. Each hair of this animal is of three different colours—the root is of a greyish brown, the middle red, or of an ash colour, and the ends white. This whiteness at the ends takes up so small a part of the particular hair that it does not prevent us from seeing the principal colour, which is that in the middle part; so that it only makes the surface of the body appear as if it were silvered over; however, the hair of which the spots consist has no white at the ends, and at the roots it is not quite so black as the other part. This animal is not above the size of the ounce, but is rather stronger built; it has but twenty-eight teeth, whereas all the rest of the cat kind already mentioned have thirty.

Another animal of this kind is called the "siagush," or, as Mr. Buffon names it, the "caracal." It is a native of the East Indies, and resembles the lynx in size, in form, and even in the singularity of being tufted at the tips of the ears. However, the siagush differs in not being mottled as the lynx is; its fur, or rather hair, is rougher and shorter; its tail is rather longer, its muzzle more lengthened, its physiognomy more fierce, and its nature more savage.

The third and last animal of this kind that need be mentioned is that which Mr. Buffon calls the "serval," and which he has first described. It is a native of Malabar, resembling the panther in its spots, but more resembling the lynx in the shortness of its tail, in its size, and in its strong-built form.

These seem to be all the principal distinctions among animals of the panther kind, from the largest of this tribe down to the domestic cat, which is the smallest of all these fierce and mischievous varieties. In all their nature seems pretty much the same—being equally fierce, subtle, cruel, and cowardly. The panther, including the leopard and the jaguar, or American panther, as they are the largest, so also are they the most dangerous of this kind—for the whole race of cats are noxious in proportion to their power to do mischief. They inhabit the most torrid latitudes of India, Africa, and America, and have never been able to multiply beyond the torrid zone. They are generally found in the thickest and the most entangled forests, and often near remote habitations, where they watch to surprise all kinds of domestic animals. They very seldom attack man, even though provoked by him; they rather seem desirous of finding safety by flight, or by climbing trees, at which they are very expert. In this manner they often pursue their prey; and, being expert at seizing it as well above as below, they cause a vast destruction. Of all animals these are most sullen, and even to a proverb untameable. They still preserve their fierce and treacherous spirit; and at those places where they are exposed to be seen among others, we often observe that while their keeper is familiar with the lion or the bear, yet he is apprehensive of the large panther, and keeps it bound with the largest chain.

As the ounce differs from these in figure and size, so also it seems to differ in disposition, being more mild, tractable, and tame. These we frequently see as harmless and innocent as domestic cats; and there is one at present in the Tower with which the keeper plays without the smallest apprehension. I confess I was not a little uneasy at first for the man, when he put his hand through the bars and called the animal by its name; but was a good deal surprised to see the creature, which one might suppose irritated by long confinement, come gently up to him, stroke his hand with its face, in the manner of a cat, and testify the utmost gentleness of disposition. The ounce, therefore, is remarkable for being easily tamed; in fact, it is employed all over the East for the purposes of hunting. Not, indeed, but that panthers themselves are sometimes used for this purpose, but they are never thoroughly subdued like the former, being usually brought to the field in a carriage, and kept chained and caged until they are shown the gazelle or the leveret, which are their prey. These they pursue rather by three or four great springs than by running; if they seize it by this sudden effort it finds no mercy; but if it escapes from their first effort they never attempt to pursue, and appear quite disappointed and confounded at their mischance. It sometimes happens that they are so much enraged at it that they attack even their employer; and his only resource to avoid their fury is to throw them some small pieces of meat, which he has brought with him for that purpose.

The ounce, however, is not so dangerous, and is treated with more confidence and familiarity. It is usually brought to the field hood-winked behind one of the horsemen. When the game appears the ounce is instantly uncovered, and shown where it lies; upon which the fierce creature darts like an arrow to the place and seizes it at once, or, missing it, remains motionless on the place. It would be vain to attempt retrieving its disgrace by continuing the pursuit; for, although it bounds with greater agility than most other animals, yet it is slow and awkward in running, and has no means of finding the animals it pursues by the smell, as is common among those of the dog kind. From hence, therefore, it appears how much superior the European method of hunting is to that of the Asiatic; since whatever amusement this exercise affords must arise from the continuance of the chase, and from the fluctuation of doubt and expectation which raise and depress the pursuers by turns. All this an Asiatic hunter is deprived of; and his greatest pleasure can scarcely be more than what among us is called "coursing," in which the dog pursues the animal and keeps it constantly in view.

But it must not be supposed that it is from choice the Asiatics use this method of chase; for, no doubt, were dogs serviceable among them as they are in Europe they would be employed for the same purposes. But the fact is, that the extreme heat of the tropical climates produces such universal putrefaction, and sends up such various and powerful scents, that dogs are at first bewildered in the chase, and at last come to lose the delicacy of their scent entirely. They are therefore but little used in those warm countries; and what could they avail in places where almost every other animal of the forest is stronger and more rapacious? The lion, the tiger, the panther, and the ounce are all natural enemies to the dog, and attack him wherever he appears with ungovernable fury. The breed, therefore, in those places would quickly be destroyed: so that they are obliged to have recourse to those animals which are more fitted to serve them, and thus convert the ounce to those purposes for which dogs are employed in Europe.

The "catamountain," or "oelot," is one of the fiercest and, for its size, one of the most destructive animals in the world. It is, as was before observed, a native

of South America, and by no means capable of the same education as the ounce, which it more approaches in size than in disposition. Two of these, from whom Mr. Buffon has taken his description, were brought over from Carthage, and having been taken from the dam when very young were afterwards suckled by a bitch. But before they were three months old they had strength and ingratitude enough to kill and devour their nurse. Their succeeding fierceness and malignity seemed to correspond with their first efforts—for no arts could tame or soften their natures; and while they continued in their cages they still testified an unceasing disposition for slaughter. When their food was given them the male always served himself before the female ventured to touch a bit; and it was not till he was satisfied that the other began. In their savage state these animals are still more destructive; having great strength and agility, they very easily find and overtake their prey, which they pursue among the tops of the trees as well as on the ground; but what renders them still more mischievous is their unceasing appetite rather for the blood than the flesh of their prey. They suck this with the greatest avidity, but frequently leave the carcase otherwise untouched, in order to pursue other animals for the blood in like manner. They generally continue on the tops of trees, like our wild cats, where they make their nest, and often bring forth their young. When they spy any animal they can master—and there are but few in the forest but what are inferior—they dart down upon it with inevitable exactness.

The whole tribe of animals of the panther kind with long tails are chiefly inhabitants, as was said, of the torrid zone; but those of the short-tailed kind, and particularly the lynx, is principally found in the cold countries that are bordering on the pole. The lynx is chiefly to be met with in the north of Germany, Lithuania, Muscovy, Siberia, and North America. Those of the new continent, however, are rather smaller than in Europe, as is the case with almost all their quadrupeds; they are somewhat whiter also, but in other respects there is scarce any difference to be found among them. This animal has been called by some "lupus cervarius," or a creature compounded between a wolf and a stag; but for what reason is hard to guess—there is no resemblance either in shape or disposition. In its nature it exactly resembles the cat, except that, being bigger and nearly two feet long, it is bolder and fiercer. Like the cat, it climbs trees, and seeks its prey by surprise; like the cat, it is delicate and cleanly, covering its urine with its paws; and it resembles the wolf in nothing except its cry, which often deceives the hunters, and induces them to think they hear a wolf and not a lynx. This animal is also rather more delicate than the cat; and, after having once feasted upon its prey, will never return to it again, but hunts the woods for another. From hence may have arisen the common report of the lynx having of all other quadrupeds the shortest memory. This, however, is not the only idle story that has been propagated of it—as of its seeing with such perspicuity as to perceive objects through walls and mountains; as of having its urine of such a quality as to harden, and become a precious stone; with several others, propagated by ignorance or imposture.

The "siagush" and the "serval" are both so like all the rest of the cat kind in disposition, that it is but repeating the same account once more to give their distinct history. As the lynx is found only in cold countries, so the siagush is to be met with only in the warm tropical climates. It is used in the same manner as the ounce for hunting; but it seems to have a property which the other has not—namely, that of being able to overtake its prey by pursuing it. Whether this be performed by having a finer scent than the former or greater swiftness we are not informed—being only told that when it overtakes either the gazelle or the antelope it leaps upon

their backs, and, getting forward to their shoulders, scratches their eyes out, by which means they become an easy prey to the hunters. Some have called this animal the "lion's provider;" and it is said that when it calls him to pursue his prey its voice very much resembles that of one man calling to another. From hence we may conjecture that this animal pursues its prey in full cry, and that the lion only follows to partake or seize the spoil. The same account is also given of the jackal; and very probably it may be true, not only of these animals but of some others, since it is natural enough to suppose that the lion will pursue whenever he is taught to discover his prey.

We had one of these animals a few years ago sent over from the East Indies, but it was not able to endure the change of climate, and it died in a very short time after it was brought to the Tower. Whether consumed by disease or not I cannot tell, but it seemed to be much slenderer than the cat or the lynx, and its ears were much longer; however, it is a very strong creature for its size, and has been known to kill a large dog in single combat: nevertheless, it is, like all of the cat kind except the lion, remarkable for its cowardice, and will never, except in cases of necessity, attack an animal that is its equal in strength and activity. For this reason, when brought into the field and put upon a service of danger, it obstinately refuses, and is alert only in the pursuit of animals that are too feeble for resistance, or too timid to exert their strength.

From what has been said of this rapacious tribe we perceive a similitude in the manners and dispositions of them all, from the lion to the cat. The similitude of their internal conformation is still more exact—the shortness of their intestines, the number of their teeth, and the structure of their paws. The first of this class is the lion, distinguishable from all the rest by his strength, his magnitude, and his mane. The second is the tiger, rather longer than the lion, but not so tall, and known by the streaks and vivid beauty of its robe; including also the American tiger or cougar—distinguishable by its size, next that of the tiger, its tawny colour, and its spots. The third are the panther and the leopard. The fourth is the ounce, not so large as any of the former, spotted like them, but distinguishable by the cream-coloured ground of its hair and the great length of its tail, being above the length of its body. The fifth is the catamountain or tiger-cat, less than the ounce, but differing particularly in having a shorter tail, and being streaked down the back like a tiger. The sixth is the short-tailed kind—namely, the lynx, of the size of the former, but with a short tail streaked, and the tips of its ears tufted with black. The seventh is the siagush, differing from the lynx in not being mottled like it, in not being so large, and in having the ears longer, though tipped with black as before. The eighth is the serval, resembling the lynx in its form and the shortness of its tail; streaked also like it, but not having the tips of the ears tufted. Lastly, the cat, wild and tame, with all its varieties—all less than any of the former, but, like them, equally insidious, rapacious, and cruel.

This whole race may be considered as the most formidable enemy of mankind; there are others, indeed, stronger, but they are more gentle, and never offer injury till injured: there are others more numerous, but they are more feeble, and look for safety by hiding from man more than opposing him. These are the only quadrupeds that make good their ground against him, and which may be said to keep some kingdoms of the earth in their own possession. How many extensive countries are there in Africa where the wild beasts are so numerous that man is deterred from living amongst them—reluctantly giving up to the lion and the leopard extensive tracts that seem formed only for his delight!

## CHAP. II.

## ANIMALS OF THE DOG KIND.

The second class of carnivorous quadrupeds may be denominated those of the "dog kind." This class is neither so numerous nor so powerful as the former, and yet neither so treacherous, rapacious, or cowardly. This class may be principally distinguished by their claws, which have no sheath like those of the cat kind, but still continue at the point of each toe, without a capability of being stretched forward or drawn back. The nose, also, as well as the jaw, of all the dog kind is longer than in the cat; the body is in proportion more strongly made, and covered with hair instead of fur. There are many internal distinctions also—as in the intestines, which are much longer in the dog kind than in those of the cat; the eye is not formed for night vision; and the olfactory nerves are diffused in the dog kinds upon a very extensive membrane within the skull.

If we compare the natural habitudes of this class with the former, we shall find that the dog kinds are not so solitary as those of the cat, but love to hunt in company, and encourage each other with their mutual cries. In this manner the dog and the jackal pursue their prey; and the wolf and the fox, which are of this kind, though more solitary and silent among us, yet in countries where less persecuted, and where they can more fearlessly display their natural inclinations, they are found to keep together in packs, and pursue their game with alternate howlings.

Animals of the dog kind want some of the advantages of the cat kind, and yet are possessed of others in which the latter are deficient. Upon observing their claws, it will easily be perceived that they cannot like cats pursue their prey up the sides of a tree, and continue the chase among the branches: their unmanageable claws cannot stick in the bark, and thus support the body up along the trunk, as we see the cat very easily perform; whenever, therefore, their prey flies up a tree from them they can only follow it with their eyes, or watch its motions till hunger again brings it to the ground. For this reason the proper prey of the dog kind are only those animals that, like themselves, are unfitted for climbing—the hare, the rabbit, the gazelle, or the roebuck.

As they are in this respect inferior to the cat, so they exceed it in the sense of smelling, by which alone they pursue their prey with certainty of success, wind it through all its mazes, and tire it down by perseverance. It often happens, however, in the savage state, that their prey is either too much diminished or too wary to serve for a sufficient supply. In this case, when driven to an extremity, all the dog kinds can live for some time upon fruits and vegetables, which, if they do not please the palate, at least serve to appease their hunger.

Of all this tribe the dog has every reason to claim the preference, being the most intelligent of all known quadrupeds, and the acknowledged friend of mankind. The dog—independent of the beauty of his form, his vivacity, force, and swiftness—is possessed of all those qualifications that can conciliate the affections of man, and make the tyrant a protector. A natural share of courage, an angry and ferocious disposition, renders the dog in its savage state a formidable enemy to all other animals; but these readily give way to very different qualities in the domestic dog, whose only ambition seems the desire to please; he is seen to come crouching along, to lay his force, his courage, and all his useful talents at the feet of his master; he waits his orders, to which he pays implicit obedience; he consults his looks, and a single glance is sufficient to put him in motion; he is more faithful even than the most boasted among men; he is constant in his affections, friendly without interest, and grateful for the slightest favours; much more mindful of benefits received than injuries offered; he is not

driven off by unkindness; he still continues humble, submissive, and imploring—his only hope to be serviceable, his only terror to displease; he licks the hand that has been just lifted to strike him, and at last disarms resentment by submissive perseverance.

More docile than man, more obedient than any other animal, he is not only instructed in a short time, but he also conforms to the dispositions and the manners of those who command him. He takes his tone from the house he inhabits; like the rest of the domestics, he is disdainful among the great, and churlish among clowns. Always assiduous in serving his master, and only a friend to his friends, he is indifferent to all the rest, and declares himself openly against such as seem to be dependent like himself. He knows a beggar by his clothes, by his voice, or his gestures, and forbids his approach. When at night the guard of the house is committed to his care, he seems proud of the charge; he continues a watchful centinel; he goes his rounds, scents strangers at a distance, and gives them warning of his being on duty. If they attempt to break in upon his territories he becomes more fierce, flies at them, threatens, fights, and either conquers alone, or alarms those who have most interest in coming to his assistance; however, when he has conquered, he quietly reposes upon the spoil, and abstains from what he has deterred others from abusing—giving thus at once a lesson of courage, temperance, and fidelity.

From hence we see of what importance this animal is to us in a state of nature. Supposing for a moment that the species had not existed, how could man without the assistance of the dog have been able to conquer, tame, and reduce to servitude every other animal? How could he discover, chase, and destroy those that were noxious to him? In order to be secure, and to become master of all Animated Nature, it was necessary for him to begin by making a friend of a part of them—to attach such of them to himself by kindness and caresses as seem fittest for obedience and active pursuit. Thus the first art employed by man was in conciliating the favour of the dog; and the fruits of this art were the conquest and peaceable possession of the earth.

The generality of animals have greater agility, greater swiftness, and more formidable arms from Nature than man; their senses, and particularly that of smelling, are far more perfect; the having gained, therefore, a new assistant, particularly one whose scent is so exquisite as that of the dog, was the gaining a new sense—a new faculty which before was wanting. The machines and instruments which we have imagined for perfecting the rest of the senses do not approach to that already prepared by Nature, by which we are enabled to find out every animal though unseen, and thus destroy the noxious and use the serviceable.

The dog, thus useful in himself, taken into a participation of empire, exerts a degree of superiority over all animals that require human protection. The flock and the herd obey his voice more readily even than that of the shepherd or the herdsman; he conducts them, guards them, keeps them from capriciously seeking danger, and their enemies he considers as his own. Nor is he less useful in the pursuit; when the sound of the horn or the voice of the huntsman calls him to the field, he testifies his pleasure by every little art, and pursues with perseverance those animals which when taken he must not expect to divide. The desire of hunting is indeed natural to him as well as to his master, since war and the chase are the only employment of savages. All animals that live upon flesh hunt by nature; the lion and the tiger, whose force is so great that they are sure to conquer, hunt alone and without art; the wolf, the fox, and the wild dog hunt in packs, assist each other, and partake the spoil. But when education has perfected this talent in the domestic dog—and when he has been taught by man to repress his ardour, to measure his

motions, and not to exhaust his force by too sudden an exertion of it, he then hunts with method, and always with success.

Although the wild dog, such as he was before he came under the protection of mankind, is at present utterly unknown, no such animal being now to be found in any part of the world, yet there are many that from a domestic state have turned savage, and entirely pursue the dictates of Nature. In those deserted and uncultivated countries where the dog is found wild they seem entirely to partake of the disposition of the wolf; they unite in large bodies, and attack the most formidable animals of the forest—the cougar, the panther, and the bison. In America, where they were originally brought by the Europeans and abandoned by their masters, they have multiplied to such a degree that they spread in packs over the whole country, attack all other animals, and even man himself does not pass without insult. They are there treated in the same manner as all other carnivorous animals, and killed wherever they happen to come; however, they are easily tamed; when taken home, and treated with kindness and lenity, they quickly become submissive and familiar, and continue faithfully attached to their masters. They differ in this from the wolf or the fox—who, though taken never so young, are gentle only while cubs, and as they grow older give themselves up to their natural appetites of rapine and cruelty. In short, it may be asserted that the dog is the only animal whose fidelity is unshaken—the only one who knows his master and the friends of the family—the only one who instantly distinguishes a stranger—the only one who knows his name and answers to the domestic call—the only one who seems to understand the nature of subordination, and seeks assistance—the only one who when he misses his master testifies his loss by his complaints—the only one who, carried to a distant place, can find the way home—the only one whose natural talents are evident, and whose education is always successful.

In the same manner, as the dog is of the most complying disposition, so also is it the most susceptible of change in its form—the varieties of this animal being too many for even the most careful describer to mention. The climate, the food, and the education, all make strong impressions upon the animal, and produce alterations in its shape, its colour, its hair its size, and in everything but its nature. The same dog, taken from one climate and brought to another, seems to become another animal; but different breeds are as much separated to all appearance as any two animals the most distinct in nature. Nothing appears to continue constant with them but their internal conformation—different in the figure of the body, in the length of the nose, in the shape of the head, in the length and direction of the ears and tail, in the colour, the quality, and the quantity of the hair; in short, different in everything but that make of the parts which serve to continue the species, and keep the animal distinct from all others. It is this peculiar conformation, this power of producing an animal that can reproduce, that marks the kind, and approximates forms that at first sight seem never made for conjunction.

From this single consideration, therefore, we may at once pronounce all dogs to be of one kind; but which of them is the original of all the rest, which of them is the savage dog from whence such a variety of descendants have come down, is no easy matter to determine. We may easily, indeed, observe, that all those animals which are under the influence of man are subject to great variations. Such as have been sufficiently independent so as to choose their own climate, their own nourishment, and to pursue their own habits, preserve the original marks of Nature without much deviation; and it is probable that the first of these is even at this day very well represented in their descendants. But such as man has subdued—transported from one climate to another, con-

trolled in their manner of living and their food—have most probably been changed also in their forms; particularly the dog has felt these alterations more strongly than any other of the domestic kinds; for, living more like man, he may be thus said to live more irregularly also, and, consequently, must have felt all those changes that such variety would naturally produce. Some other causes may also be assigned for this variety in the species of the dog: as he is perpetually under the eye of his master, when accident has produced any singularity in its productions, man uses all his art to continue this peculiarity unchanged—either by breeding from such as had these singularities, or by destroying such as happened to want them; besides, as the dog produces much more frequently than some other animals, and lives a shorter time, so the chance for its varieties will be offered in greater proportion.

But which is the original animal and which the artificial or accidental variety is a question which, as was said, is not easily resolved. If the internal structure of dogs of different sorts be compared with each other, it will be found, except in point of size, that in this respect they are exactly the same. This, therefore, affords no criterion. If other animals be compared with the dog internally, the wolf and the fox will be found to have the most perfect resemblance; it is probable, therefore, that the dog, which most nearly resembles the wolf or the fox externally, is the original of its kind; for it is natural to suppose, that as the dog most nearly resembles them internally, so he may be near them in external resemblance also, except where art or accident has altered his form. This being supposed, if we look among the number of varieties to be found in the dog, we shall not find one so like the wolf or the fox as that which is called the "shepherd's dog." This is that dog with long coarse hair on all parts except the nose, pricked ears, and a long nose, which is common enough among us, and receives his name from being principally used in guarding and attending on sheep. This seems to be the primitive animal of his kind; and we shall be the more confirmed in this opinion if we attend to the different characters which climate produces in this animal, and the different races of dogs which are propagated in every country: in the first place, if we examine those countries which are still savage or but half civilised—where it is most probable the dog, like his master, has received but few impressions from Art—we shall find the shepherd's dog, or one very like him, still prevailing amongst them. The dogs that have run wild in America and in Congou approach this form. The dog of Siberia, Lapland, and Iceland—of the Cape of Good Hope, of Madagascar, Madura, Calicut, and Malabar—have all long noses, pricked ears, and closely resemble the shepherd's dog. In Guinea, the dog speedily takes this form; for at the second or third generation the animal forgets to bark, his ears and his tail become pointed, and his hair drops off, while a coarser, thinner kind comes in the place. This sort of dog is also to be found in the temperate climates in great abundance, particularly among those who, preferring usefulness to beauty, employ an animal that requires very little instruction to be serviceable. Notwithstanding this creature's deformity, his melancholy and savage air, he is superior to all the rest of his kind in instinct; and, without any teaching, naturally takes to tending flocks, with an assiduity and vigilance that at once astonishes and yet relieves his master.

In more polished and civilised places the dog seems to partake of the universal refinement; and, like the men, becomes more beautiful, more majestic, and more capable of assuming an education foreign to his nature. The dogs of Albany, of Greece, of Denmark, and of Ireland are larger and stronger than those of any other kind. In France, Germany, Spain, and Italy the dogs are of various kinds, like the men; and this variety seems

formed by crossing the breed of such as are imported from various climates.

The shepherd's dog may therefore be considered as the primitive stock from whence these varieties are all derived: he makes the stem of that genealogical tree which has been branched out into every part of the world. This animal still continues pretty nearly in its original state among the poor in temperate climates; being transported into the colder regions, he grows less and more ugly among the Laplanders, but becomes more perfect in Iceland, Russia, and Siberia, where the climate is less rigorous and the people more civilised. Whatever differences there may be among the dogs of these countries they are not very considerable, as they have all straight ears, long and thick hair, a savage aspect, and do not bark either so often or so loud as dogs of the more cultivated kind.

The shepherd's dog, transported into the temperate climates, and among people entirely civilised, such as England, France, and Germany, will be divested of his savage air, his pricked ears, his rough, long, and thick hair, and from the single influences of climate and food alone, will become either a matin, a mastiff, or a hound. These three seem the immediate descendants of the former; and from them the other varieties are produced.

The "hound," the "harrier," and the "beagle" seem all of the same kind; for although the bitch is covered but by one of them, yet in her litters are found puppies resembling all the three. This animal, transported into Spain or Barbary, where the hair of all quadrupeds becomes soft and long, will be there converted into the land-spaniel and the water-spaniel, and these of different sizes.

The "grey matin hound," which is in the second branch, transported to the north, becomes the great Danish dog; and, sent into the south, it becomes the greyhound of different sizes. The same, transported into Ireland, the Ukraine, Tartary, Epirus, or Albany, becomes the great wolf-dog, known by the name of the "Irish wolf-dog."

The "mastiff," which is the third branch, and chiefly a native of England, when transported into Denmark becomes the little Danish dog; and this little Danish dog, sent into the tropical and warm climates, becomes the animal called the "Turkish dog," without hair. All these races, with their varieties, are produced by the influence of climate, joined to the different food, education, and shelter which they have received among mankind. All other kinds may be considered as mongrel races produced by the concurrence of these, and found rather by crossing the breed than by attending to the individual. As these are extremely numerous and very different in different countries, it would be almost endless to mention the whole; besides, nothing but experience can ascertain the reality of these conjectures, although they have so much the appearance of probability; and until that gives more certain information we must be excused from entering more minutely into the subject.

With regard to the dogs of our country in particular, the varieties are very great, and the number every day increasing. And this must happen in a country so open by commerce to all others, and where wealth is apt to produce capricious predilection. Here the ugliest and the most useless of their kinds will be entertained merely for their singularity; and, being imported only to be looked at, they will lose even that small degree of sagacity which they possessed in their natural climates. From this importation of useless foreign dogs our own native breed is, I am informed, greatly degenerated, and the varieties now to be found in England are much more numerous than in the time of Queen Elizabeth, when Dr. Caius attempted their natural history. Some of those he mentions are no longer to be found among us, although many have since been introduced which

are by no means so serviceable as those that have been suffered to decay.

He divides the whole race into three kinds. The first is the generous kind, which consists of the terrier, the harrier, and the blood-hound—the gaze-hound, the greyhound, the leymmer, and the tumbler; all these are used for hunting. Then the spaniel, the setter, and the water-spaniel or finder, were used for fowling; and the spaniel-gentle or lap-dog for amusement. The second is the farm kind, consisting of the shepherd's dog and the mastiff. And the third is the mongrel kind, consisting of the wappe, the turnspit, and the dancer. To these varieties we may add at present the bull-dog, the Dutch mastiff, the harlequin, the pointer, and the Dano, with a variety of lap-dogs, which, as they are perfectly useless, may be considered as unworthy of a name.

The terrier is a small kind of hound, with rough hair, made use of to force the fox or the badger out of their holes—or rather, to give notice by their barking in what part of their kennel the fox or the badger resides when the sportsmen intend to dig them out.

The harrier as well as the beagle and the fox-hound is used for hunting; of all other animals they have the quickest and most distinguishing sense of smelling. The properly breeding, matching, and training these make up the business of many men's lives.

The blood-hound was a dog of great use and in high esteem among our ancestors. Its employ was to recover any game that had escaped from the hunter, or had been killed or stolen out of the forest. But it was still more employed in hunting thieves and robbers by their foot-steps. At that time, when the country was less peopled than at present, and when, consequently, the footsteps of one man was less crossed and obliterated by those of others, this animal was very serviceable in such pursuits: but at present, when the country is everywhere peopled, this variety is quite worn out—probably because it was found of less service than formerly.

The gaze-hound hunted, like our greyhounds, by the eye and not by the scent. It chased indifferently the fox, hare, or buck. It would select from the herd the fattest and fairest deer, pursue it by the eye, and if lost recover it again with amazing sagacity. This species is now lost or unknown among us.

The greyhound is very well known at present, and was formerly held in such estimation that it was the peculiar companion of a gentleman, who in the times of semi-barbarism was known by his horse, his hawk, and his greyhound. Persons under a certain rank of life are forbidden from keeping this animal; wherefore to disguise it the better they cut off its tail.

The leymmer is a species now unknown to us. It hunted both by scent and sight, and was led in a leyme or thong, from whence it received its name.

The tumbler was less than the hound, more scraggy, and had pricked ears; so that by the description it seems to answer to the modern lurcher. This took its prey by mere cunning, depending neither on the goodness of its nose nor its swiftness. If it came into a warren it neither barked nor ran on the rabbits; but, seemingly inattentive, approached sufficiently near till it came within reach, and then seized them by a sudden spring.

The land-spaniel—which probably had its name from Spain, where it might have acquired the softness of its hair—is well known at present. There are two varieties of this kind—namely, the slater, used in hawking to spring the game; and the setter, that crouches down when he scents the birds till the net be drawn over them. I have read somewhere that the famous poet, Lord Surrey, was the first who taught dogs to set—it being an amusement to this day only known in England.

The water-spaniel was another species used in fowling. This seems to be the most docile of all the dog kind; and this docility is particularly owing to his natural attachment to man. Many other kinds will not bear

correction; but this patient creature, though very fierce to strangers, seems unalterable in his affections, and blows and ill usage seem only to increase his regard.

The lap-dog, in the time of Dr. Caius, was of Maltese breed; at present it comes from different countries; in general, the more awkward or extraordinary these are the more they are prized.

The shepherd's dog has been already mentioned; and as for the mastiff, he is too common to require a description. Dr. Caius informs us that three of these were reckoned a match for a bear, and four for a lion. However, we are told that three of them overcame a lion in the time of King James the First; two of them being disabled in the combat, the third obliged the lion to seek for safety by flight.

As to the last division, namely, of the wrappe, the turnspit, and the dancier, these were mongrels of no certain shape, and made use of only to alarm the family, or, being taught a variety of tricks, were carried about as a show.

With regard to those of later importation, the bull-dog, as Mr. Buffon supposes, is a breed between the small Dane and the English mastiff. The large Dane is the tallest dog that is generally bred in England. It is somewhat between a mastiff and a greyhound in shape, being more slender than the one and much stronger than the other. They are chiefly used rather for show than service, being good neither in the yard nor the field. The highest are most esteemed; and they generally cut off their ears to improve their figure, as some absurdly suppose. The harlequin is not much unlike the small Dane, being an useless animal, somewhat between an Italian greyhound and a Dutch mastiff. To these several others might be added, such as the pug-dog, the black breed, and the pointer; but, in fact, the varieties are so numerous as to fatigue even the most ardent curiosity.

Of those of the foreign kind I shall mention only three, which are more remarkable than any of the rest. The lion-dog greatly resembles that animal in miniature, from whence it takes the name. The hair of the fore-part of its body is extremely long, while that of the hinder part is as short. The nose is short, the tail long, and tufted at the point, so that in all these particulars it is entirely like the lion. However, it differs very much from that fierce animal in nature and disposition, being one of the smallest animals of its kind, extremely feeble, timid, and inactive. It comes originally from Malta, where it is found so small that women carry it about in their sleeves.

That animal falsely called the "Turkish dog" differs greatly from the rest of the kind, in being entirely without hair. The skin, which is perfectly bare, is of a flesh-colour, with brown spots; and their figure at first view is rather disgusting. These seem to be of the small Danish breed, brought into a warm climate, and there, by a succession of generations, divested of their hair. For this reason they are extremely chilly, and unable to endure the cold of our climate; and even in the midst of summer they continue to shiver as we see men do in a frosty day. Their spots are brown, as was said, well-marked, and easily distinguishable in summer, but in the cold of winter they entirely disappear. They are called the Turkish breed, although brought from a much warmer climate; for some of them have been known to come from the warmest parts of Africa and the East Indies.

The last variety, and the most wonderful of all that I shall mention, is the great Irish wolf-dog, that may be considered as the first of the canine species. This animal, which is very rare even in the only country in the world where it is to be found, is rather kept for show than use, there being neither wolves nor any other formidable beasts of prey in Ireland that seem to require so powerful an antagonist. The wolf-dog is therefore bred up in the houses of the great, or such gentlemen as

choose to keep him as a curiosity, being neither good for hunting the hare, the fox, or the stag, and equally unserviceable as a house-dog. Nevertheless he is extremely beautiful and majestic in appearance, being the greatest of the dog kind to be seen in the world. The largest of those I have seen, and I have seen above a dozen, was about four feet high, or as tall as a calf of a year old. He was made extremely like a greyhound, but rather more robust, and inclining to the figure of the French mastiff or the great Dane. His eye was mild, his colour white, and his nature seemed heavy and phlegmatic. This I ascribed to his having been bred up to a size beyond his nature; for we see in man and all other animals that such as are overgrown are neither so vigorous nor alert as those of more moderate stature. The greatest pains have been taken with these to enlarge the breed, both by food and matching. This end was effectually obtained, indeed, for the size was enormous, but, as it seemed to me, at the expense of the animal's fierceness, vigilance, and sagacity. However, I was informed otherwise—the gentlemen who bred them assuring me that a mastiff would be nothing when opposed to one of them, who generally seized their antagonist by the back; he added, that they would worry the strongest bull-dogs to death in a few minutes. But this strength did not appear either in their figure or their inclinations; they seemed rather more timid than the ordinary race of dogs; and their skin was much thinner, and consequently less fitted for combat. Whether with these disadvantages they were capable, as I was told, of singly coping with bears, others may determine; however, they have but few opportunities in their own country of exerting their strength, as all wild carnivorous animals there are only of the vermin kind. Mr. Buffon seems to be of opinion that these are the true Molossian dogs of the ancients; he gives no reason for this opinion; and I am apt to think it ill-grounded. Not to trouble the reader with a tedious critical disquisition, which I have all along avoided, it will be sufficient to observe that Nemesianus, in giving directions for the choice of a bitch, advises to have one of Spartan or Molossian breed; and, among several other perfections, he says that the ears should be dependent, and fluctuate as she runs. This, however, is by no means the case with the Irish wolf-dog, whose ears resemble those of the greyhound, and are far from fluctuating with the animal's motions. But of whatever kinds these dogs may be, whether known among the ancients or whether produced by a later mixture, they are now almost quite worn away, and are very rarely to be met with even in Ireland. If carried to other countries they soon degenerate; and even at home, unless great care be taken, they quickly alter. They were once employed in clearing the island of wolves, which infested it in great plenty; but these being destroyed the dogs also are wearing away, as if Nature meant to blot out the species when they had no longer any service to perform.

In this manner several kinds of animals fade from the face of Nature that were once well known, but are now seen no longer. The enormous elk of the same kingdom—which by its horns could not have been less than eleven feet high—the wolf, and even the wolf-dog, are extinct, or only continued in such a manner as to prove their former plenty and existence. From hence, it is probable that many of the nobler kinds of dogs of which the ancients have given us such beautiful descriptions are now utterly unknown; since among the whole breed we have not one that will venture to engage the lion or the tiger in single combat. The English bull-dog is perhaps the bravest of the kind; but what are his most boasted exploits to those mentioned of the Epirotic dogs by Pliny, or the Indian dogs by Ælian? The latter gives us a description of a combat between a dog and a lion, which I will take leave to translate:—

When Alexander was pursuing his conquests in India,

one of the principal men of that country was desirous of showing him the value of the dogs which that country produced. Bringing his dog into the king's presence he ordered a stag to be let loose before him, which the dog despised as an unworthy enemy, remained quite regardless of the animal, and never once stirred from his place. His master then ordered a wild boar to be set out; but the dog thought even this a despicable foe, and remained calm and regardless as before. He was next tried with a bear; but, still despising his enemy, he only waited for an object more worthy of his courage and his force. At last they brought forth an enormous lion, and then the dog acknowledged his antagonist and prepared for combat. He instantly discovered a degree of ungovernable ardour, and, flying at the lion with fury, seized him by the throat, and totally disabled him from resistance. Upon this, the Indian, who was desirous of surprising the king, and knowing the constancy and bravery of his dog, ordered his tail to be cut off—which was easily performed, as the bold animal was employed in holding the lion. He next ordered one of his legs to be broken—which, however, did not in the least abate the dog's ardour, but he still kept his hold as before. Another leg was then broken; but the dog, as if he had suffered no pain, only pressed the lion still the more. In this cruel manner, all his legs were cut off without abating his courage; and at last, when even his head was separated from his body, the jaws seemed to keep their former hold. A sight so cruel did not fail to affect the king with strong emotions, at once pitying the dog's fate and admiring his fortitude; upon which the Indian, seeing him thus moved, presented him with four dogs of the same kind, which in some measure alleviated his uneasiness for the former.

The breed of dogs, however, in that country is at present very much inferior to what this story seems to imply; since in many places instead of dogs they have animals of the cat kind for hunting. In other places, also, this admirable and faithful animal, instead of being applied to his natural uses, is only kept to be eaten. All over China there are dog-butchers, and shambles appointed for selling their flesh. In Canton in particular there is a street appropriated for that purpose; and, what is very extraordinary, wherever a dog-butcher appears all the dogs of the place make war upon him, and are sure to be in full cry after him; they know their enemy, and persecute him as far as they are able. But among this barbarous and brutal people scarce anything that has life comes amiss; and they may well take up with a dog, since they consider toads, lizards, and even the flesh of the tiger itself, as a dainty. It may, perhaps, happen that the flesh of this animal, which is so indifferent in the temperate climates, may assume a better quality in those which are more warm; but it is more than probable that the diversity is rather in man than in the flesh of the dog; since in the cold countries the flesh is eaten with equal appetite by the savages, and they have their dog-feasts in the same manner as we have ours for venison.

In our climate, the wild animals that most approach the dog are the wolf and the fox; these in their internal conformation greatly resemble each other, and yet in their natures are very distinct. The ancients asserted that they bred together; and I am assured by credible persons that there are many animals in this country bred between a dog and a fox. However, all the endeavours of Mr. Buffon to make them engender, as he assures us, were ineffectual. For this purpose he bred up a young wolf, taken in the woods at two months old, with a matron dog of the same age. They were shut up together without any other in a large yard, where they had a shelter for retiring. They neither of them knew any other individual of their kind, nor even any other man but he who had the charge of feeding them. In this manner they were kept for three years; still with the same attention, and

without constraining or tying them up. During the first year the young animals played with each other continually, and seemed to love each other very much. In the second year they began to dispute about their victuals, although they were given more than they could use. The quarrel always began on the wolf's side. They were brought their food, which consisted of flesh and bones, upon a large wooden platter, which was laid on the ground. Just as it was put down, the wolf, instead of falling to the meat, began by driving off the dog; and took the platter in its teeth so expertly, that it let nothing of what it contained fall upon the ground, and in this manner carried it off; but as the wolf could not entirely escape, it was frequently seen to run with the platter round the yard five or six times, still carrying it in a position that none of its contents could fall. In this manner it would continue running, only now and then stopping to take breath, until the dog coming up, the wolf would leave the victuals to attack him. The dog, however, was the stronger of the two, but as it was more gentle, in order to secure him from the wolf's attack he had a collar put round his neck. In the third year the quarrels of these ill-paired associates were more vehement and their combats more frequent; the wolf, therefore, had a collar put round its neck as well as the dog, who began to be more fierce and unmerciful. During the two first years neither seemed to testify the least tendency toward engendering; and it was not till the end of the third that the wolf, which was the female, showed the natural desire, but without abating either in its fierceness or obstinacy. This appetite rather increased than repressed their mutual animosity; they became every day more untractable and ferocious, and nothing was heard between them but sounds of rage and resentment. They both in less than three weeks became remarkably lean, without ever approaching each other but to combat. At length, their quarrels became so desperate that the dog killed the wolf, who was become more weak and feeble; and he was soon after himself obliged to be killed, for, upon being set at liberty, he instantly flew upon every animal he met—fowls, dogs, and even men themselves not escaping his savage fury.

The same experiments were tried upon foxes, taken young, but with no better success—they were never found to engender with dogs; and our learned naturalist seems to be of opinion that their natures are too opposite ever to provoke mutual desire. One thing, however, must be remarked, that the animals on which he tried his experiments were rather too old when taken, and had partly acquired their natural savage appetites before they came into his possession. The wolf, as he acknowledges, was two or three months old before it was caught, and the foxes were taken in traps. It may therefore be easily supposed that nothing could ever after thoroughly tame these creatures that had been suckled in the wild state, and had caught all the habitudes of the dam. I have seen these animals when taken earlier in the woods become very tame; and, indeed, they rather were displeasing by being too familiar than too shy. It were to be wished that the experiment were tried upon such as these; and it is more than probable that it would produce the desired success. Nevertheless, these experiments are sufficient to prove that neither the wolf nor the fox are of the same nature with the dog, but each of a species perfectly distinct, and their joint produce most probably unfruitful.

The dog when first whelped is not a completely finished animal. In this kind, as in all the rest that bring forth many at a time, the young are not so perfect as in those which bring forth one or two. They are always produced with the eyes closed, the lids being held together, not by sticking, but by a kind of thin membrane, which is torn as soon as the upper eye-lid becomes strong enough to raise it from the under. In general their eyes are not opened till ten or twelve days old. During that

time the bones of the skull are not completed, the body is puffed up, the nose is short, and the whole form but ill sketched out. In less than a month the puppy begins to use all its senses, and from thence makes hasty advances towards perfection. At the fourth month the dog loses some of his teeth, as in other animals, and these are renewed by such as never fall. The number of these amount to forty-two, which is twelve more than is found in any of the cat kind, which are known never to have above thirty. The teeth of the dog, being his great and only weapon, are formed in a manner much more serviceable than those of the former; and there is scarce any quadruped that has a greater facility in rending, cutting, or chewing its food. He cuts with his incisors or fore-teeth, he holds with his four great canine teeth, and he chews his meat with his grinders; these are fourteen in number, and so placed, that when the jaws are shut there remains a distance between them—so that the dog, by opening his mouth ever so wide, does not lose the power of his jaws. But it is otherwise in the cat kind, whose incisors or cutting-teeth are very small, and whose grinding-teeth when brought together touch more closely than those of the dog, and, consequently, have less power. Thus, for instance, I can squeeze anything more forcibly between my thumb and fore-finger, where the distance is greater, than between any other two fingers whose distance from each other is less.

This animal is capable of reproducing at the age of twelve months; goes nine weeks with young, and lives to about the age of twelve. Few quadrupeds are less delicate in their food; and yet there are many kinds of birds which the dog will not venture to touch. He is even known, although in a savage state, to abstain from injuring some which one might suppose he had every reason to oppose. The dogs and the vultures which live wild about Grand Cairo in Egypt (for the Mahometan law has expelled this useful animal from human society) continue together in a very sociable and friendly manner. As they are both useful in devouring such carcases as might otherwise putrefy, and thus infect the air, the inhabitants supply them with provisions every day in order to keep them near the city. Upon these occasions the quadrupeds and birds are often seen together, tearing the same piece of flesh without the least enmity; on the contrary, they are known to live together with a kind of affection, and bring up their young in the same nest.

Although the dog is a voracious animal, yet he can bear hunger for a long time. We have an instance in the Memoirs of the Academy of Sciences of this kind, in which a bitch, that had been forgotten in a country-house, lived forty days without any other nourishment than the wool of a quilt which she had torn in pieces. It would seem that water is more necessary for the dog than food; he drinks often but not abundantly; and it is commonly believed that when abridged in water he runs mad. This dreadful malady, the consequences of which are so well known, is the greatest inconvenience that results from the keeping this faithful domestic. But it is a disorder by no means so frequent as the terrors of the timorous would suppose; the dog has often been accused of madness without a fair trial; and some persons have been supposed to receive their deaths from his bite, when either their own ill-grounded fears or their natural disorders were the true cause.

**THE WOLF.**—The dog and the wolf are so very much alike internally, that the most expert anatomists can scarce perceive the difference; and it may be asserted, also, that externally some dogs more nearly resemble the wolf than they do each other. It was this strong similitude that first led some naturalists to consider them as the same animal and to look upon the wolf as the dog in its state of savage freedom: however, this opinion is

entertained no longer; the natural antipathy those two animals bear to each other—the longer time which the wolf goes with young than the dog, the one going over a hundred days, and the other not quite sixty—the longer period of life in the former than the latter, the wolf living twenty years, the dog not fifteen—all sufficiently point out a distinction, and draw a line that must for ever keep them asunder.

The wolf from the tip of the nose to the insertion of the tail is about three feet seven inches long, and about two feet five inches high; which shows him to be larger than our great breed of mastiffs, which are seldom found to be above three feet by two. His colour is a mixture of black, brown, and grey, extremely rough and hard, but mixed towards the roots with a kind of ash-coloured fur. In comparing him to any of our well-known breed of dogs, the great Dane or mongrel greyhound, for instance, he will appear to have the legs shorter, the head larger, the muzzle thicker, the eyes smaller and more separated from each other, and the ears shorter and straighter. He appears in every respect stronger than the dog; and the length of his hair contributes still more to his robust appearance. The feature which principally distinguishes the visage of the wolf from that of the dog is the eye, which opens slantingly upwards in the same direction with the nose; whereas in the dog it opens more at right angles with the nose, as in man. The tail, also, in this animal is long and bushy; and he carries it rather more between his hind-legs than the dog is seen to do. The colour of the eye-balls in the wolf are of a fiery green, and give his visage a fierce and formidable air, which his natural disposition by no means contradicts.

The wolf is one of those animals whose appetite for animal food is the most vehement, and whose means of satisfying this appetite are the most various. Nature has furnished him with strength, cunning, agility, and all those requisites which fit an animal for pursuing, overtaking, and conquering its prey; and yet, with all these the wolf most frequently dies of hunger, for he is the declared enemy of man. Being long proscribed, and a reward offered for his head, he is obliged to fly from human habitations, and to live in the forest, where the few wild animals to be found there escape him either by their swiftness or their art; or are supplied in too small a proportion to satisfy his rapacity. He is naturally dull and cowardly; but being frequently disappointed, and as often reduced to the verge of famine, he becomes ingenious from want and courageous from necessity. When pressed with hunger he braves danger, and comes to attack those animals which are under the protection of man, particularly such as he can readily carry away—lambs, sheep, or even dogs themselves, for all animal food becomes then equally agreeable. When this excursion has succeeded he often returns to the charge, until, having been wounded or hard pressed by the dogs or the shepherds, he hides himself by day in the thickest coverts, and only ventures out at night; he then sallies forth over the country, keeps peering round the villages, carries off such animals as are not under protection, attacks the sheep-folds, scratches up and undermines the thresholds of doors where they are housed, and worries and destroys all before he begins to fix upon and carry off his prey. When these sallies do not succeed he returns to the thickest part of the forest, content to pursue those smaller animals which, even when taken, afford him but a scanty supply. He there goes regularly to work, follows by the scent, opens to the view, still keeps following, hopeless himself of overtaking the prey, but expecting that some other wolf will come in to his assistance, and then content to share the spoil. At last, when his necessities are very urgent, he boldly faces certain destruction; he attacks women and children, and sometimes ventures even to fall upon men, becomes furious by his continual agitations, and ends his life in madness.

The wolf, as well externally as internally, so nearly resembles the dog that he seems modelled upon the same plan; and yet he only offers the reverse of the medal. If his form be like, his nature is so different, that he only preserves the ill qualities of the dog without any of his good ones. Indeed, they are so different in their dispositions that no two animals can have a more perfect antipathy to each other. A young dog shudders at the sight of a wolf; he even shuns his scent, which, though unknown, is so repugnant to his nature, that he comes trembling to take protection near his master. A dog who is stronger, and who knows his strength, bristles up at the sight, testifies his animosity, attacks him with courage, endeavours to put him to flight, and does all in his power to rid himself of a presence that is hateful to him. They never meet without either flying or fighting—fighting for life and death, and without mercy on either side. If the wolf is the stronger he tears and devours his prey; the dog, on the contrary, is more generous, and contents himself with his victory; he does not seem to think that "the body of a dead enemy smells well;" he leaves him where he falls, to serve as food for birds of prey or for other wolves, since they devour each other; and when one wolf happens to be desperately wounded the rest track him by his blood, and are sure to show him no mercy.

The dog even in his savage state is not cruel; he is easily tamed; and continues firmly attached to his master. The wolf when taken young becomes tame, but never has any attachment: Nature is stronger in him than education; he resumes with age his natural dispositions, and returns as soon as he can to the woods from whence he was taken. Dogs, even of the dullest kinds, seek the company of other animals; they are naturally disposed to follow and accompany other creatures not of their own genus; and even by instinct, without any education, take to the care of flocks and herds. The wolf, on the contrary, is the enemy of all society; he does not even keep much company with those of his own kind. When they are seen in packs together it is not to be considered as a peaceful assemblage, but a combination for war; they testify their hostile intentions by their loud howlings, and by their fierceness discover a project for attacking some great animal, such as a stag or a bull, or to destroy some redoubtable watchdog. The instant their war-like expedition is completed their society is at an end; they then part, and each returns to his solitary retreat. There is not even any strong attachment between the male and the female; they seek each other only once a year, and remain but a few days together; they always couple in winter—at which time several males are seen following one female, and this association is still more bloody than the former: they dispute violently—growl, bark, fight, and tear each other; and it sometimes happens that the majority kill the wolf which has been preferred by the female. It is usual for the she-wolf to fly from them all with him she has chosen, and watches her opportunity when the rest are asleep.

The season for coupling does not continue above twelve or fifteen days, and usually commences among the oldest—those which are young being later in their desires. The males have no fixed time for engendering; they pass from one female to the other, beginning at the end of December, and ending at the latter end of February. The time of pregnancy is about three months and a half; and the young wolves are found from the latter end of April to the beginning of July. The long continuance of the wolf's pregnancy is sufficient to make a distinction between it and the dog, did not also the fiery fierceness of the eyes, the howl instead of barking, and the greater duration of its life, leave no doubt of its being an animal of its own particular species. In other respects, however, they are entirely alike; the wolf couples exactly like the dog, the parts are

formed in the same manner, and their separation hindered by the same cause. When the she-wolves are near their time of bringing forth they seek some very tufted spot in the thickest part of the forest; in the middle of this they make a small opening, cutting away the thorns and briars with their teeth, and afterwards carrying thither a great quantity of moss, which they form into a bed for their young ones. They generally bring forth five or six, and sometimes even nine, at a litter. The cubs are brought forth, like those of the bitch, with the eyes closed; the dam suckles them for some weeks, and teaches them betimes to eat flesh, which she prepares for them by chewing it first herself. Some time afterwards she brings them stronger food—hares, partridges, and birds yet alive. The young wolves begin by playing with them, and end by killing them. The dam then strips them of their feathers, tears them in pieces, and gives to each of them a share. They do not leave the den where they have been littered till they are six weeks or two months old. They then follow the old one, who leads them to drink to the trunk of some old tree where the water has settled, or at some pool in the neighbourhood. If she apprehends any danger she instantly conceals them in the first convenient place, or brings them back to their former retreat. In this manner they follow her for some months; when they are attacked she defends them with all her strength, and more than usual ferocity. Although at other times more timorous than the male, at that season she becomes bold and fearless—solicitous, perhaps, to teach the young ones future courage by her own example. It is not till they are about ten or twelve months old, when they have shed the old teeth and completed the new, that she thinks them in a capacity to shift for themselves. Then, when they have acquired arms from Nature, and have learned industry and courage from her example, she declines all future care of them, being again engaged in bringing up a new progeny.

The males and females are in a capacity to engender when two years old. It is probable that the females of this species, as well as of most others, are sooner completed than the males; but this is certain, that they never desire to copulate until their second winter; from whence we may suppose that they live fifteen or twenty years; for, allowing three years for their complete growth, this multiplied by seven gives them a life of twenty-one—most animals, as has been observed, living about seven times the number of years which it takes them to come to perfection. Of this, however, there is as yet no certainty, no more than of what huntsmen assert—that in all the litters there are more males than females. From them we also learn that there are some of the males who attach themselves to the female, who accompany her during her gestation until the time of bringing forth, when she hides the place of her retreat from the male lest he should devour her cubs; but after this, when they are brought forth, that he then takes the same care of them as the female, carries them provisions, and, if the dam should happen to be killed, rears them up in her stead.

The wolf grows grey as he grows old, and his teeth wear, like those of most other animals, by using. He sleeps when his belly is full or when he is fatigued, rather by day than night; and, like the dog, is very easily waked. He drinks frequently; and in times of draught, when there is no water to be found in the trunks of old trees or in the pools about the forest, he comes often in the day down to the brooks or the lakes in the plain. Although very voracious he supports hunger for a long time, and often lives four or five days without food, provided he be supplied with water.

The wolf has great strength, particularly in his fore parts, in the muscles of his neck and jaws. He carries off a sheep in his mouth without letting it touch the ground, and runs with it much swifter than the shepherd

who pursue him; so that nothing but the dogs can overtake and oblige him to quit his prey. He bites cruelly, and always with greater vehemence in proportion as he is least resisted; for he uses precautions with such animals as attempt to stand upon the defensive. He is ever cowardly, and never fights but when under the necessity of satisfying hunger or making good his retreat. When he is wounded by a bullet he is heard to cry out; and yet, when surrounded by the peasants and attacked with clubs, he never howls as the dog under correction, but defends himself in silence, and dies as hard as he lived.

His nature is, in fact, more savage than that of the dog; he has less sensibility and greater strength. He travels, runs, and keeps plundering for whole days and nights together. He is in a manner indefatigable; and perhaps of all animals he is the most difficult to be hunted down. The dog is good natured and courageous; the wolf, though savage, is ever fearful. If he happens to be caught in a pit-fall he is for some time so frightened and astonished that he may be killed without offering to resist, or taken alive without much danger. At that moment one may clap a collar round his neck, muzzle him, and drag him along, without his giving the least signs of anger or resentment. At all other times he has his senses in great perfection—his eye, his ear, and particularly his sense of smelling, which is even superior to the two former. He smells a carcass at more than a league's distance; he also perceives living animals a great way off, and follows them a long time on the scent. Whenever he leaves the wood he always takes care to go out against the wind. When just come to its extremity, he stops on all sides to examine by his smell the emanations that may come either from his enemy or his prey, which he very nicely distinguishes. He prefers those animals which he kills himself to those he finds dead; and yet he does not disdain these when no better is to be had. He is particularly fond of human flesh—and, no doubt, if he was sufficiently powerful he would eat no other. Wolves have been seen following armies, and arriving in numbers on the field of battle, where they devoured such dead bodies as were left upon the field or but negligently interred. These, when once accustomed to human flesh, ever seek particularly to attack mankind, and choose to fall upon the shepherd rather than his flock. We have had a late instance of two or three of these keeping a whole province for more than a month in a continual alarm.

It sometimes happens that a whole country is called out to extirpate these most dangerous invaders. The hunting the wolf is a favourite diversion among the great in some countries; and it must be admitted it seems to be the most rational of any. These animals are distinguished by the huntsmen into the "young wolf," the "old wolf," and the "great wolf." They are known by the prints of their feet—the older the wolf the larger the track he leaves; that of the female is narrower and longer than that of the male. It is necessary to have a good starter to put up the wolf; and it is even convenient to use every art to encourage him in this pursuit—for all dogs have a natural repugnance to this animal, and are but cold in their endeavours. When the wolf is once put up it is then proper to have greyhounds to let fly at him, in leashes, one after the other. The first leash is sent after him in the beginning, accompanied by a man on horseback; the second is let loose about half a mile further, and the third when the rest of the dogs come up with and begin to bait him. He for a long time keeps them off, stands his ground, threatens them on all sides, and frequently gets away; but usually the hunters arrive in aid of the dogs, and despatch him with their cutlasses. When the animal is killed the dogs testify no appetite to enjoy their victory, but leave him where he falls—a loathsome and hideous spectacle even in death.

The wolf is also sometimes hunted with harriers; but as he always goes straight forward, and often holds his speed for a whole day together, this kind of chase is tedious and disagreeable, at least if the harriers are not assisted by greyhounds, who may harass him at every view. Several other arts have also been used to take and destroy this noxious animal. He is surrounded and wounded by men and large house-dogs; he is inveigled into traps; he is poisoned by carcasses prepared for that purpose; and is caught in pit-falls. Gesner tells us of a friar, a woman, and a wolf being taken in one of these all in the same night. The woman lost her reason through fright, the friar his reputation, and the wolf his life. All these disasters, however, do not prevent this animal's multiplying in great numbers, particularly in countries where woods abound. France, Spain, and Italy are greatly infested with them; but England, Ireland, and Scotland are happily set free.

King Edgar is said to have been the first who endeavoured to rid this country of such disagreeable inmates, by commuting the punishment for certain crimes into the acceptance of a number of wolves' tongues from each criminal. However, some centuries after these animals increased to such a degree as to again become the object of royal attention; accordingly, Edward I. issued out his mandate to one Peter Corbet to superintend and assist in their destruction. They are said to have infested Ireland long after they were extirpated in England. The oldest men in that country, however, remember nothing of these animals; and it is probable that there have been none there for more than a century past. Scotland is similarly situated.

The colour of this animal differs according to the different climates where it is bred, and often changes even in the same country. Beside the common wolves which are found in France and Germany, there are others with thicker hair, inclining to yellow. These are more savage and less noxious than the former, approaching neither flocks nor habitations, and living rather by the chase than rapine. In the northern climates they are found some quite black, and some white all over. The black wolves are larger and stronger than those of any other kind.

The species is very much diffused in every part of the world, being found in Asia, Africa, and in America, as well as Europe. The wolves of Senegal resemble those of France, except that they are larger and much fiercer than those of Europe. Those of Egypt are smaller than those of Greece. In the East the wolf is trained up for a show, being taught to dance and play tricks; one of these thus educated often sells for four or five hundred crowns. It is said that in Lapland this animal will never attack a rein-deer that is haltered; for they are so well acquainted with the nature of a trap that they suspect one whenever they perceive a rope. However, when they see the deer at liberty they seldom fail to destroy it.

The wolf of North America is blacker and much less than those in other parts of the world, and approaches nearer to the dog in form than those of the ordinary kind. In fact, they were made use of as such by the savages till the Europeans introduced others; and even now, on the remoter shores or the more inland parts of the country, the savages still make use of these animals in hunting. They are very tame and gentle; and those that are wild are neither so large nor so fierce as an European wolf—nor do they ever attack mankind. They go together by night in large packs to hunt the deer, which they do as well as any dogs in England; and it is confidently asserted that one of them is sufficient to run down a deer. Whenever they are seen along the banks of those rivers near which the wandering natives pitch their huts, it is taken for granted that the bison or the deer are not far off; and the savages affirm that the wolves come with the tidings in order to

have the garbage after the animal has been killed by the hunters. Catesby adds a circumstance relative to these animals which, if true, invalidates many of Mr Buffon's observations. He asserts that, these being the only dogs used by the Americans before the arrival of the Europeans among them, they have since engendered together, and that their breed has become prolific; which proves the dog and the wolf to be of the same species. It were to be wished that this opinion were better ascertained, and we should then know to a certainty in what degree the dog and wolf resemble each other, as well in nature as in conformation; we might then, perhaps, be enabled to improve the breed of our dogs by bringing them back to their native forms and instincts; we might, by crossing the strain, restore that race of those bold animals which the ancients assure us were more than a match for the lion.

However this animal may be useful in North America, the wolf of Europe is a very noxious animal, and scarce anything belonging to him is good except his skin, of which the furriers make a covering that is warm and durable, though coarse and unsightly. His flesh is very indifferent, and seems to be disliked by all other animals, no other creature being known to eat wolves' flesh except the wolf himself. He emits a most fetid vapour from his jaws, as his food is indiscriminate, often putrid, and seldom cleanly. In short, every way offensive—a hideous howl, an unbearable odour, a perverse disposition, and fierce habits—he is hateful while living and useless when dead.

**THE FOX.**—The fox exactly resembles the wolf and the dog internally; and although he differs greatly from both in size and carriage, yet when we come to examine his shape minutely there will appear to be but a trifling difference in the description. Were, for instance, a painter to draw from a natural historian's most exact description the figure of a dog, a wolf, and a fox, without having ever seen either, he would be apt to confound all these animals together—or rather, he would be unable to catch those peculiar outlines that no description can supply. Words will never give any person an exact idea of forms any way irregular; for although they be extremely just and precise, yet the numberless discriminations to be attended to will confound each other, and we shall no more conceive the precise form than we should be able to tell when one pebble more was added or taken away from a thousand. To conceive, therefore, how the fox differs in form from the wolf or the dog, it is necessary to see all three, or at least to supply the defects of description by examining the difference in a print.

The fox is of a more slender make than the wolf, and not near so large; for as the former is above three feet and a half long, so the other is not above two feet three inches. The tail of the fox, also, is longer in proportion and more bushy; its nose is smaller, and approaching more nearly to that of the greyhound, and its hair softer. On the other hand, it differs from the dog in having its eyes obliquely situated, like those of the wolf; its ears are directed also in the same manner as those of the wolf, and its head is equally large in proportion to its size. It differs still more from the dog in its strong offensive smell, which is peculiar to the species, and often the cause of their death. However, some are ignorantly of opinion that it will keep off infectious diseases, and they preserve this animal near their habitations for that very purpose.

The fox has since the beginning been famous for his cunning and his arts, and he partly merits his reputation. Without attempting to oppose either the dogs or the shepherds, without attacking the flock or alarming the village, he finds an easier way to subsist, and gains by his address what is denied to his strength or courage. Patient and prudent, he waits the opportunity of depre-

dation, and varies his conduct with every occasion. His whole study is his preservation; although nearly as indefatigable, and actually more swift than the wolf, he does not entirely trust to either, but makes himself an asylum, to which he retires in case of necessity, where he shelters himself from danger and brings up his young.

As among men, those who lead a domestic life are more civilised and more endued with wisdom than those who wander from place to place; so, in the inferior ranks of animated nature, the taking possession of a home supposes a degree of instinct which others are without. The choice of the situation for this domicile, the art of making it convenient, of hiding its entrance, and securing it against more powerful animals, are all so many marks of superior skill and industry. The fox is furnished with both, and turns them to his advantage. He generally keeps his kennel at the edge of the wood, and yet within an easy journey of some neighbouring cottage. From thence he listens to the crowing of the cock and the cackling of the domestic fowls. He scents them at a distance; he seizes his opportunity, conceals his approaches, creeps slyly along, makes the attack, and seldom returns without his booty. If he be able to get into the yard he begins by levelling all the poultry without remorse, and, carrying off a part of the spoil, hides it at some convenient distance, and again returns to the charge. Taking off another fowl in the same manner he hides that also, but not in the same place; and this he practises for several times together, until the approach of day or the noise of the domestics give him warning to retire. The same arts are practised when he finds birds entangled in springes laid for them by the fowler; the fox takes care to be beforehand, very expertly takes the bird out of the snare, hides it for three or four days, and knows exactly when and where to return to avail himself of the hidden treasure. He is equally alert in seizing the young hares and rabbits before they have strength enough to escape him, and when the old ones are wounded and fatigued he is sure to come upon them in their moments of distress, and to show them no mercy. In the same manner he finds out birds' nests, seizes the partridge and the quail while sitting, and destroys a large quantity of game. The wolf is most hurtful to the peasant, but the fox to the gentleman. In short, nothing that can be eaten seems to come amiss—rats, mice, serpents, toads, and lizards. He will when urged by hunger eat vegetables and insects; and those that live near the sea-coasts will for want of food eat crabs, shrimps, and shell-fish. The hedge-hog in vain rolls itself up into a ball to oppose him; this determined glutton teizes it until it is obliged to appear uncovered, and then he devours it. The wasp and the wild bee are attacked with equal success. Although at first they fly out upon the invader, and actually oblige him to retire, this is but for a few minutes, until he has rolled himself upon the ground, and thus crushed such as stick to his skin; he then returns to the charge, and at last by perseverance obliges them to abandon their combs, which he greedily devours, both wax and honey.

The chase of the fox requires less preparation than that of the wolf, and it is also more pleasant and amusing. As dogs have a natural repugnance to pursue the wolf, so they are equally alert in following the fox, which they prefer even to the chase of the hare or the buck. The huntsmen, as upon other occasions, have their cant terms for every part of this chase. The fox the first year is called a "cub;" the second, a "fox;" and the third, an "old fox;" his tail is called the "brush" or "drag," and his excrement the "billiting." He is usually pursued by a large kind of harrier or hound, assisted by terriers, or a smaller breed that follow him into his kennel and attack him there. The instant he perceives himself pursued he makes to his kennel, and takes refuge at the bottom of it, where for a while he loses the cry of his

enemies; but the whole pack, coming to the mouth, redouble their vehemence and rage, and the little terrier boldly ventures in. It often happens that the kennel is made under a rock, or among the roots of old trees; and in such cases the fox cannot be dug out, nor is the terrier able to contend with him at the bottom of his hole. By this contrivance he continues secure; but when he can be dug out the usual way is to carry him in a bag to some open country, and there set him loose before the hounds. The hounds and the men follow, barking and shouting wherever he runs; and the body being strongly employed, the mind has not time to make any reflection on the futility of the pursuit. What adds to this entertainment is the strong scent which the fox leaves, which always keeps up a full cry; although as his scent is stronger than that of the hare it is much sooner evaporated. His shifts to escape when all retreat is cut off to his kennel are various and surprising. He always chooses the most woody country, and takes those paths that are most embarrassed with thorns and briars. He does not double, nor use the unavailing shifts of the hare, but flies in a direct line before the hounds, though at no very great distance—manages his strength—takes to the low and plashy grounds, where the scent will be less apt to lie; and at last, when overtaken, he defends himself with desperate obstinacy, and fights in silence to the very last gasp.

The fox, though resembling the dog in many respects, is nevertheless very distinct in its nature, refusing to engender with it; and though not testifying the antipathy of the wolf, yet discovering nothing more than indifference. This animal also brings forth fewer at a time than the dog, and that but once a year. Its litter is generally from four to six, and seldom less than three. The female goes with young about six weeks, and seldom stirs out while pregnant, but makes a bed for her young, and takes every precaution to prepare for their production. When she finds the place of their retreat discovered, and that her young have been disturbed during her absence, she removes them one after the other in her mouth, and endeavours to find them out a place of better security. A remarkable instance of this animal's parental affection happened while I was writing this history in the county of Essex. A she-fox that had, as it would seem, but one cub, was unkenelled by a gentleman's hounds near Chelmsford, and hotly pursued. In such a case, when her own life was in imminent peril, one would think that it was not a time to consult the safety of her young; however, the poor animal, braving every danger, rather than leave her cub behind to be worried by the dogs, took it up in her mouth and ran with it in this manner for some miles. At last, making her way through a farmer's yard, she was assaulted by a mastiff, and at last obliged to drop her cub, which was taken up by the farmer. I was not displeased to hear that this faithful creature escaped the pursuit, and at last got off in safety. The cubs of the fox are born blind like those of the dog; they are eighteen months or two years in coming to perfection, and live about twelve or fourteen years.

As the fox makes war upon all animals, so all others seem to make war upon him. The dog hunts him with peculiar acrimony; the wolf is still a greater and more necessitous enemy, who pursues him to his very retreat. Some pretend to say that to keep the wolf away the fox lays at the mouth of its kennel a certain herb to which the wolf has a particular aversion. This, which no doubt is a fable, at least shows that these two animals are as much enemies to each other as to the rest of Animated Nature. But the fox is not hunted by quadrupeds alone; for the birds, who know him for their mortal enemy, attend him in his excursions, and give each other warning of their approaching danger. The daw, the magpie, and the blackbird conduct him along, perching on the hedges as he creeps below, and, with their cries and notes of hostility, apprise all other animals to beware—a caution

which they perfectly understand, and put into practice. The hunters themselves are often informed by the birds of the place of his retreat, and set the dogs into those thickets where they see them particularly noisy and querulous. So that it is the fate of this petty plunderer to be detested by every rank of animals; all the weaker classes shun, and all the stronger pursue him.

The fox of all wild animals is most subject to the influence of the climate; and there are found as many varieties in this kind almost as in any of the domestic animals. The generality of foxes, as is well known, are red; but there are some, though not in England, of a greyish cast; and Mr. Buffon asserts that the tip of the tail in all foxes is white; which, however, is not so in those of this country. There are only three varieties of this animal in Great Britain, and these are rather established upon a difference of size than of colour or form. The greyhound fox is the largest, tallest, and boldest, and will attack a grown sheep; the mastiff fox is less, but more strongly built; the cur fox is the least and most common—he lurks about hedges and out-houses, and is the most pernicious of the three to the peasant and the farmer.

In the colder countries round the pole the foxes are of all colours—black, blue, grey, iron grey, silver grey, white, white with red legs, white with black heads, white with tip of the tail black, red with the throat and belly entirely white, and, lastly, with a stripe of black running along the back and another crossing it at the shoulders. The common kind, however, is more universally diffused than any of the former, being found in Europe, in the temperate climates of Asia, and also in America; they are very rare in Africa, and in the countries lying under the torrid zone. Those travellers who talk of having seen them at Calicut and other parts of Southern India have mistaken the jackal for the fox. The fur of the white fox is held in no great estimation, because the hair falls off. The blue fox skins are bought up with great avidity, from their scarceness; but the black fox skin is of all others the most esteemed, a single skin often selling for forty or fifty crowns. The hair of these is so disposed that it is impossible to tell which way the grain lies; for if we hold the skin by the head the hair hangs to the tail, and if we hold it by the tail it hangs down equally smooth and even to the head. These are often made into females' muffs, and are at once very beautiful and warm. In our temperate climate, however, furs are of very little service, there being scarce any weather so severe in England from which our ordinary clothes may not very well defend us.

**THE JACKAL.**—The jackal is one of the commonest wild animals in the East; and yet there is scarce any less known in Europe, or more confusedly described by natural historians. In general we are assured that it resembles the fox in figure and disposition; but we are still ignorant of those nice distinctions by which it is known to be of a different species. It is said to be of the size of a middling dog, resembling the fox in the hinder parts, particularly the tail, and the wolf in the fore-parts, especially the nose. Its legs are shorter than those of the fox, and its colour is of a bright yellow, or sorrel, as we express it in horses. This is the reason it has been called in Latin the "golden wolf"—a name, however, which is entirely unknown in the countries where they are most common.

The species of the jackal is diffused all over Asia, and is also found in most parts of Africa—seeming to take up the place of the wolf, which in those countries is not so common. There seem to be many varieties among them; those of the warmest climates appear to be the largest, and their colour is rather of a reddish brown than of that beautiful yellow by which the smaller jackals are chiefly distinguished.

Although the species of the wolf approaches very near

to that of the dog, yet the jackal seems to be placed between them; to the savage fierceness of the wolf it adds the impudent familiarity of the dog. Its cry is a howl, mixed with barking, and a lamentation resembling that of human distress. It is more noisy in its pursuits even than the dog, and more voracious than the wolf. The jackal never goes alone, but always in a pack of forty or fifty together. These unite regularly every day to form a combination against the rest of the forest. Nothing then can escape them; they are content to take up with the smallest animals; and yet, when thus united, they have courage to face the largest. They seem very little afraid of mankind, but pursue their game to the very doors without testifying either attachment or apprehension. They enter insolently into the sheepfolds, the yards, and the stables, and, when they can find nothing else, devour the leather harness, boots, and shoes, and run off with what they have not time to swallow.

They not only attack the living but the dead. They scratch up with their feet the new-made graves, and devour the corpse no matter how putrid. In those countries, therefore, where they abound they are obliged to beat the earth over the grave and mix it with thorns, to prevent the jackals from scraping it away. They always assist each other, as well in this employment of exhumation as in that of the chase. While they are at this dreary work they exhort each other by a mournful cry, resembling that of children under chastisement; and when they have thus dug up the body they share it amicably between them. These, like all other savage animals, when they have once tasted human flesh can never after refrain from pursuing mankind. They watch the burying-grounds, follow armies, and keep in the rear of caravans. They may be considered as the vulture of the quadruped kind; everything that once had animal life seems equally agreeable to them; the most putrid substances are greedily devoured; dried leather, and anything that has been rabbed with grease, how insipid soever in itself, is sufficient to make the whole go down.

They hide themselves in holes by day, and seldom appear abroad till night-fall, when the jackal that has first hit upon the scent of some larger beast gives notice to the rest by a howl, which it repeats as it runs; while all the rest that are within hearing pack in to its assistance. The gazelle, or whatever other beast it may be, finding itself pursued, makes off towards the houses and the towns; hoping by that means to deter its pursuers from following; but hunger gives the jackal the same degree of boldness that fear gives the gazelle, and it pursues even to the verge of the city, and often along the streets. The gazelle, however, by this means most frequently escapes; for the inhabitants sallying out often disturb the jackal in the chase; and as it hunts by the scent, when once driven off it never recovers it again. In this manner we see how experience prompts the gazelle—which is naturally a very timid animal, and particularly fearful of man—to take refuge near him, considering him as the least dangerous enemy, and often escaping by his assistance.

But man is not the only intruder upon the jackal's industry and pursuits. The lion, the tiger, and the panther, whose appetites are superior to their swiftness, attend to its call, and follow in silence at some distance behind. The jackal pursues the whole night with unceasing assiduity, keeping up the cry, and with great perseverance at last tires down its prey; but just at the moment it supposes itself going to share the fruits of its labour, the lion or the leopard comes in, satiates himself upon the spoil, and his poor provider must be content with the bare carcase he leaves behind. It is not to be wondered at, therefore, if the jackal be voracious, since it so seldom has a sufficiency; nor that it feeds on putrid substances, since it is not permitted to feast on what it has newly killed. Besides these enemies the jackal has another to cope with—for between him and the dog

there is an irreconcilable antipathy, and they never part without an engagement. The Indian peasants often chase them as we do foxes, and have learned by experience when they have got a lion or a tiger in their rear. Upon such occasions they keep their dogs close, as they would be no match for such formidable animals, and endeavour to put them to flight by their cries. When the lion is dismissed they more easily cope with the jackal, who is as stupid as it is impudent, and seems much better fitted for pursuing than retreating. It sometimes happens that one of them steals silently into an out-house to seize the poultry or devour the furniture, but hearing others in full cry at a distance, without thought it instantly answers the call, and thus betrays its own depredations. The peasants sally out upon it, and the foolish animal finds too late that its instinct was too powerful for its safety.

**THE ISATIS.**—As the jackal is a sort of intermediate species between the dog and the wolf, so the isatis may be considered as placed between the dog and the fox. This animal has hitherto been supposed to be only a variety of the latter; but from the latest observations there is no doubt of their being perfectly distinct. The isatis is very common in all the northern countries bordering upon the Icy Sea, and is seldom found except in the coldest countries. It very much resembles a fox in the form of its body and the length of its tail, and a dog in the make of its head and the position of its eyes. The hair of these animals is softer than that of a common fox; some are blue, some are white at one season, and at another of a russet brown. Although the whole of its hair is two inches long, thick, tufted, and glossy, yet the under jaw is entirely without any, and the skin appears bare in that part.

This animal can bear only the coldest climates, and is chiefly seen along the coasts of the Icy Sea, and on the banks of the great rivers that discharge themselves therein. It is fond of living in the open country, and is seldom seen in the forest, being mostly found in the mountainous and naked regions of Norway, Siberia, and Lapland. It burrows like the fox; and when wit's young, the female retires to her kennel in the same manner as the fox is seen to do. These holes, which are very narrow and extremely deep, have many outlets. They are kept very clean, and are bedded at the bottom with moss for the animal to be more at its ease. Its manner of coupling, time of gestation, and number of young, are all similar to what is found in the fox; and it usually brings forth at the end of May or the beginning of June.

Such are the particulars in which this animal differs from those of the dog kind and in which it resembles them; but its most striking peculiarity remains still to be mentioned—namely, its changing colour, and being seen at one time brown and at another perfectly white. As was already said, some are naturally blue, and their colour never changes; but such as are to be white are when brought forth of a yellow hue, which in the beginning of September is changed to white, all except along the top of the back, along which runs a stripe of brown, and another crossing it down the shoulders, at which time the animal is called the "crossed fox;" however, this brown cross totally disappears before winter, and then the creature is all over white, and its fur is two inches long; this about the beginning of May again begins to fall; and the moulting is completed about the middle of July, when the isatis becomes brown once more. The fur of this animal is of no value unless it be killed in winter.

**THE HYÆNA.**—The hyæna is the last animal I shall mention among those of the dog kind, which it in many respects resembles, although too strongly marked to be strictly reduced to any type. The hyæna is nearly of the

size of a wolf, and has some similitude to that animal in the shape of its head and body. The head at first sight does not appear to differ, except that the ears of the hyæna are longer, and with less hair; but upon observing more closely we shall find the head broader, the nose flatter, and not so pointed. The eyes are not placed obliquely, but more like those of a dog. The legs, particularly the hinder, are longer than those either of the dog or the wolf, and different from all other quadrupeds in having but four toes, as well on the fore-feet as on the hinder. Its hair is of a dirty greyish, marked with black, disposed in waves down its body. Its tail is short, with pretty long hair; and immediately under it, above the anus, there is an opening into a kind of glandular pouch, which separates a substance of the consistence but not of the colour of civet. This opening might have given rise to the error of the ancients, who asserted that this animal was every year alternately male and female. Such are the most striking distinctions of the hyæna as given us by naturalists—which, nevertheless, convey but a very confused idea of the peculiarity of its form. Its manner of holding its head seems remarkable—somewhat like a dog pursuing the scent with its nose near the ground. The head being held thus low, the back appears elevated like that of the hog, which, with a long bristly band of hair that runs all along, gives it a good deal the air of that animal; and it is probable that from this similitude it first took its name—the word “huoïna” being Greek, and derived from “hus,” which signifies a sow.

But no words can give an adequate idea of this animal's figure, deformity, and fierceness; more savage and untameable than any other quadruped, it seems to be for ever in a state of rage or rapacity—for ever growling, except when receiving its food. Its eyes then glisten, the bristles of its back all stand upright, its head hangs low, and yet its teeth appear—all which give it a most frightful aspect, and which a dreadful howl tends to heighten. This, which I have often heard, is very peculiar; its beginning resembles the voice of a man moaning, and its latter part as if he were making a violent effort to vomit. As it is loud and frequent, it might, perhaps, have been sometimes mistaken for that of a human voice in distress, and have given rise to the accounts of the ancients, who tell us that the hyæna makes its moan to attract unwary travellers, and then to destroy them: however this be, it seems the most untractable and, for its size, the most terrible of all other quadrupeds; nor does its courage fall short of its ferocity; it defends itself against the lion, is a match for the panther, attacks the ounce, and seldom fails to conquer.

It is an obscene and solitary animal, to be found chiefly in the most desolate and uncultivated parts of the torrid zone, of which it is a native. It resides in the caverns of mountains, in the clefts of rocks, or in dens that it has formed for itself under the earth. Though taken never so young it cannot be tamed; it lives by depredation, like the wolf, but is much stronger and more courageous. It sometimes attacks man, carries off cattle, follows the flock, breaks open the sheep-cots by night, and ravages with insatiable voracity. Its eyes shine by night; and it is asserted, not without great appearance of truth, that it sees better by night than by day. When destitute of other provision, it scrapes up the graves and devours the dead bodies, how putrid soever. To these dispositions, which are sufficiently noxious and formidable, the ancients have added numberless others, which are long since known to be fables—as, for instance, that the hyæna was male and female alternately; that having brought forth and suckled its young, it then changed sexes for a year and became a male. This, as was mentioned above, could only proceed from the opening under the tail, which all animals of this species are found to have, and which is found in the same manner in no other quadruped except the badger.

There is in the weasel kind indeed an opening, but it is lower down, and not placed above the anus, as in the badger and the hyæna. Some have said that this animal changed the colour of its hair at will; others, that a stone was found in its eye, which, put under a man's tongue, gave him the gift of prophecy; some have said that it had no joints in the neck, which, however, all quadrupeds are known to have; and some, that the shadow of the hyæna kept dogs from barking. These, among many other absurdities, have been asserted of this quadruped, and which I mention to show the natural disposition of mankind to load those that are already but too guilty with accumulated reproach.

### CHAP. III.

#### OF ANIMALS OF THE WEASEL KIND.
